Hi Dan,

I would imagine its noodle-like quality of strength would be a give
away. Simple test: hold the prospective element out horizontal
(holding it at one end). How much does it bend? I've had thick wall
aluminum tubing that folded like a kimono sash.

Now, only you knows how much bend is too much (or you will shortly
find out when you put it up - take notes).

Hi Gary,

Reason? Reason for what? I was not fooled and the power as indicated by BOTH meters is, as you put it and show it and demonstrate it, 15-20W.

You have shown nothing with a dependance upon discrimination in voltages. The statement that there is some value at which
> the voltage is much higher than the current
begs the question: how much is too much? Put a number to it and let's see.

Does the assertion that "we do not get a pure sine wave out" mean
that the sources are non-linear?

It always works the way I think it does, Gary. :-) It works if the
necessary boundary conditions are met, i.e. it must be used in a
50 ohm environment (for a meter calibrated at 50 ohms) e.g. a 50
ohm transmission line where V+/I+ = 50 ohms and V-/I- = 50 ohms.

I have mine sitting on a 12 foot pipe beside the garage. It
works
like a hot damn! The coax runs down the pipe and along the
ground
into my shack basement window. I don't take any special
lightning
precautions because (1) a direct hit doesn't care what
precautions
you take, (2) I should be able to repair any damage in the
black
box as there is good info on the net on the box contents,
and
(3) I only paid $100 Canadian for it! A lovely antenna in
my
opinion. It has withstood numerous high winds and ice here
in
the cold Alberta winter!

Shit or get off the pot then. We have heard this for months. I suspect
he and many others will be waiting for a long, long, time. Do you and
your goofball lawyers "if you really have any" ever actually sue anyone?
Seems to me if they had a case, they would be jumping all over it.
I suspect after their evaluation of this ongoing dilemma, they informed
you that you have no case at all.

Gary, K4FMX wrote:
"---adding two powers together is different from "increasing" a power by 3 db."

The two powers added together must be each the same as the original power considered.

Gary also wrote:
"Key each transmitter individually and you will see 100 watts from either transmitter on the wattmeter. Key them both and you will see something greater than 200 watts."

First, the wattmeter readings may not be accurate.

Second, the impedance seen by a transmitter is a big factor in power output. Two transmitters need to see a total output impedance of twice or half the impedance for a single transmitter depending upon their effective connection, series or parallel, so that each transmitter can deliver its maximum outpot.

Gary also wrote:
"You can not directly add two powers together."

Your electric power company is doing so as you read this. Multiple generators are directly paralleled supplying paralleled multiple loads. As the total resistance drops, they add generators to keep up with the demand. It works!

Gary also wrote:
"--when the two signals are combined we do not get a pure sine wave out. It is a complex wave."

Not if the two signals are pure sine waves of the same frequency. Such sine waves merge seamlessly into a single pure sine wave. A distorted wave has additional frequency components.

Best regards, Richard Harrison, KB5WZI

Bird will probably advise you to limit the reflected power to 0-10% of forward power for accuracy within their specified accuracy (without a look-up I believe it`s a respectable 5%). Beyond the limits, the "wattmeter" is an indicator of watts.

What is obvious? By only looking at the second meter can you tell me
directly from the meter reading how much power is being reflected
from the resistor to the tuner?

Raj,
If I recall correctly, the instruction that came
with my R-7 said that a mounting height of 4 feet was
recommended. electrically, the R-7 presents a short
to ground at frequencies below RF, the antenna is always
grounded (if ground mounted on a metalic support).
Despite what is claimed by Cushcraft, all antennas
benefit from a good ground system under them.

OK. I found appendix 5 and my reaction was, What`s this? Think of what the electric company does and my analysis is correct.

Then it dawned! appendix 5 is a statistical summation of unrelated powers like busy-hour traffic loading. Haven`t confirmed that from other curves and tables. It`s been 20-30 yrs since I was usimg that sort of addition for equipment loading and level setting. Statistics aren`t fresh in my mind, but I`ve used curves just like those in Saveskie`s book and it`s essentially noise loading. It`s different from combining sinewaves of the same frequency.

Best regards, Richard Harrison, KB5WZI

Hi Walt,
The section on pages 98-101 has to do with the solution for E at some distance x from the generator given in terms of Eg, Zg, and Zr. Eqn 4.23 appears to be just a general expression for the voltage at an arbitrary distance from the generator. Johnson's comment (p. 100) with regard to Eqn 4.23 has to do with it being in the form (E+) + (E-), where E+ is the net incident (forward) wave consisting of the sum of all the individual waves traveling toward the load. E- is a similar term for the net wave representing the sum of the waves traveling (backward) toward the generator. The equation can be divided into 2 terms, one in e^(-gamma*X) which would be the forward voltage wave component, and the other one in e^(+gamma*X) which would be the backward voltage wave component.

StarGazer <pti@capnet.com> verbositized:

>how do you know it had harmonics all over the place.

Because I was running a packet station on that antenna and wiped out the whole net one night until I received a phone call telling me I was running packet on the wrong frequency. I was on the right frequency, but at the same time, I found out after some testing, I was on many frequencies.
At first I thought something was wrong with my transmitter and it went broadband on me, so I pulled it and used a different radio, again the same problem occurred.
Back then I didn't have a means to check much of anything. But switching back over to the brass antenna caused no problems.
Reconnecting back to the nickel plated antenna I could pick up my signal on many frequencies across the band and also on some bands I wasn't even on. It was so long ago that I don't remember the exact details anymore, but I did have quite a few people mad at me for months over that issue.

The particular pipe I had used was 3/8 inch hard copper, nickel plated. It was nickel plated for later chrome plating apparently, by the company I got it from, but they were supposed to have used soft copper rather than hard for the intended purpose. So to them, it was waste scrap taking up space and I got it for like 1/4th the price of new copper pipe.

I can't say with all honesty that the nickel coating is what truly caused the problem, because I don't really know for sure. But since it was identical in all aspects to another yagi I had built that worked perfectly, the antenna itself became suspect and was discarded.
I later used a piece of that same pipe as a stub on a J-Pole and we never could get the antenna antenna SWR down.
In both cases, received signal strength (at a listening station) was way down on the antennas with nickel plated components.
I do remember losing a lot of packets on that antenna before I got the phone call, but that is about all I remember about it. Other than it took solder real well, hi hi.....

No, you can't roll it up. If you have excess ladder line when you get from your antenna to your rig, you just cut the excess off.
Run ladder line from the antenna to the entrance to the shack. Transition to 50 ohm coax to your tuner. Put a 1:1 current balun on the coax. Try to keep the coax length as short as possible, say less than 10'.
In the coax vs. ladder line debate, that's one for coax, you can roll coax up.

Is this still the AS-2 antenna? I suspect you can simply cut it to the
desired length. I don't see that it is a tuned feeder of any sort.
Can't roll it up.

Sorry, in the case of combining the two transmitters, for clarity I
should have said, that they are
on two separate frequencies. 1 mhz apart will do.

This is a real world situation as I described, it is done every day.
Usually with more than two
transmitters (Very common with cell sites and trunking systems) but
the same outcome applies.
The total power out on the antenna line watt meter reads more than the
sum of the power of all
transmitters.

Each transmitter sees an almost flat 50 ohm load as it goes directly
into an isolator before going
to the cavity and T junction. Measuring the power right out of the
transmitter before the isolator
will show the transmitters full power and almost zero reflected.

When I said "You can not directly add two powers together." I was
speaking of mathematically.
As in 1 plus 1 = 2

Hi Richard,

This is a little hard to take, you are dismissing the evidence of your
own man?

Read Appendix 5 again and tell me where it mutters even a centilla of
> statistical summation of unrelated
>powers like busy-hour traffic loading.
that is out of the blue! Mine is a first edition if that has any
bearing on the matter of Appendices being renumbered (look up "db
power, addition" in the table of contents).

There is nothing in his discussion that stands outside of the standard
usage of dBm, dBW or the like.

To simplify his examples and show the error of this addition consider:
0dBm + 0dBm = 3dBm
clearly
0 + 0
does not offer 3 as a choice in any system of mathematics (except by
virtue of being dBm and through the agencies of Saveskie's graph).

Saveskie merely offers a cautionary entry into the hazards of adding
dBm and he thus provides correction curves that are entirely derivable
from the math, no sophisticated statistics required.

Myself, I am convinced you are confused as to what is under
discussion.
0dBm + 0dB = 0dBm
0dBm + 0dBm = 3dBm
0dBm + 3dB = 3dBm
the only two that conform to simple math (Bill's concern and the
entire point of appendix 5) are those where powers are NOT added.

Hmmmmmm, you mean if a resistor is dissipating 1 watt and 1 watt is added to the dissipation, the result is not 2 watts? Hmmmmmmm

If you raise the voltage from 1v to 1.414v, then the power dissipation doubles? 1^2 * 1 = 1? 1.414^2 * 1 = 2? 1w + 1w = 2w? Of all the things in the entire consideration, the energy is the single thing that must be conserved. You can add 100v to 100v and get anything between zero volts and 200 volts but you cannot fool Mother Nature as far as energy is concerned. If you add 100v to 100v and get zero volts, energy must be conserved. If you add 100v to 100v and get 200 volts, energy must be conserved. Mother Nature doesn't care about volts. Mother Nature cares about joules. She told me so Herself.

1. Six meters is a place in the Radio Spectrum that has the unique ability to act like HF (High Frequencies) and VHF (Very High Frequencies). In otherwords it can be wide open or totally dead.

For new comers the most exciting mode would be Sporadic E (E Skip). This is usually quite loud and easy to work with simple equipment, low power and small antenna's.

For the more exotic modes. Such as Meteor Showers, Trans-equatorial, F-layer skip more sophisticated equipment would be necessary most of the time.

It is refered to as 'the magic band'.

2. These antenna plots are for reference only. They can and do become quite different in 'real world' environs. Use them as a guide only. DB gain......use the figures given in DBd (Decible over a DIPOLE). That is the only realistic figure you can use. DBi (isotropic) is a fictious point in space, that does not actually exist. And can not actually be measured.

3. A 'gamma match' is a device used to transform the impedeance of the driven element of a yagi type antenna to properly match the coaxial line. It consists of a variable capacitor coupled in series with the center conductor of the coax line. This is then spaced from the driven element. The cold end of this capacitor (usually made from aluminum tubing) is connected at the proper point along the driven element. The space, the position of the tap, and the amount of capacitance all contribute to making the proper transformation.

4. There are several ELMER lists available on the internet. You might want to try looking it up under Google. Or probably someone here can direct you in the proper direction.

Joining a local club would probably be a good start. Since one on one help is usually more effective.

5. Of course....didn't you know that to be a ham required a certain amount of 'crazyness' ?? Just ask any hams wife.

Have fun

98% of the time its the latter.
No offense to the 6 meter gang...I once worked Chile with a Heathkit
Sixer and a homemade dipole hanging in the window.

Cut the ladder line. So it is just long enough to reach from your antenna to
your shack equipment. You don't need all the excess.

3175. Ladderline wrapped around fiberglass?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-08-17 02:44:05 UTC
From: marvin rosen <raghead@worldnet.att.net>
Message-ID: <VLi79.16026$Ep6.1250846@bgtnsc05-news.ops.worldnet.att.net>
Source record: 136616

I'm constructing a dipole 100' long. The center of this dipole
will be held up by a 10' fiberglass 2" diameter pole. Can i wrap
the ladderline around the pole as long as there is seperation between
adjoining turns of ladderline? I then plan on connecting a 1:1
current balun at the base & then coax to a tuner in the shack.
Is there a minimum of ladderline i should use?

Outgoing mail is certified Virus Free.

The way I read this is that your ladder-line will only be about 10 feet
long. How long will the coax be?

My long wire antenna of about half that length and coupled through an automatic tuner works on all bands between 10 and 80.

That should be OK. Fiberglass makes a pretty good coil form. Keep
the turns at least 3 inches apart and the negative effect should be
relatively small.

If the SWR on the ladder-line is not 1:1, you will never see 450 ohms.
For instance, if the SWR is 10:1 and you are feeding at a current maximum
point, the impedance looking into the ladder-line will be 45 ohms. Your
4:1 balun will try to take that impedance down to 11 ohms when it was
already near perfect at 45 ohms.

Check out the all-band-HF-antenna on my web page to see what can be done
by choosing a good length for the ladder-line.

Allow me to share some of my E mail. Yes I know you all probably got e
mail on Unwin antenna and it's previous thread.
#1 Surely all is known when you couple two simple antennas? The
experts have
given a 'thumbs down'.Accept it.
Well sir, on its face it seams clear and easy but it is more
complicated than it
appears. The experts come from a variety of backgrounds and it cannot
be expected that each on his own could give an intelligent response.
Where-as I
because of past medical problems had to re-educate myself. And where I
chose a task that was pertinent to my needs i.e. a deep but narrow
education to solve
multi frequency problems.I have no doubt in my mind that if two or
more entered into a debate on the apparently rediculous claims I made,
a firm resolution will be quickly found in my favour. Remember the
loop design is older than I am and is surrounded by myths. It was
displaced by the arrival of the Yagi and was then decimated by
A.J.Henk G4XVF. Not many really understand the nuances of the loop
design (no offence intended to members of the group)
#2 The drawing is so simple. What makes you think that you are on to
something
that has escaped others.
Well you can have all the experts and those with theories lined up to
talk about the posabilities of some thing new. comming from the other
side of the pond I am still tied to the old ways and until somebody
gets a piece of wire and proves it to himself, all the ideas fall to
the ground. I have made such an antenna and a ham friend made one for
himself without me being present and duplicated my results. I call
that compelling evidence.
#3 This one from overseas, call sign unknown and was more insightfull
than most.
It stated that at no time except for one person have shown
you(me)disrespect.
Clarke may be different but again no evidence of disrespect (hmmmmm).
'Doc' on
the other hand does not participate in any discussion that requires
interaction of depth. You do not have to go far into the archives to
determine what manner of person he is because he has trashed others.On
your side you started the thread expecting a problem since it is said
you have raised this subject before.
It would apear that all studied your claims and all deny the
plausability of your claims.
In defence I say that not one has come forward to state exactly what

happens when co-joining basic radiators Fact is that there is so many interlocking factors that my detractors have no idea of what could or could not happen and i mean no disrespect.As for 'Doc' I respected his presence because of credentials implied. Yes it would have been different if he signed off with hospital orderly,bed pan collector e.t.c..As far as him having a history I noted that others did not align themselves with him. I now note that that he states that is not a real doctor (he is a fraud) so I see no need to waste my time in the archives.
#4 The experts know what happens in the simple case you offered. Accept the verdict and go away. Sir I cannot because I believe in myself and it follows laws ennunciated by the likes of Maxwell.

Reg,
How come I have this feeling that you, who thrives on the basics
especially in regard to loop antennas, is sitting there with a smile
on your face and a computor program in hand just waiting for when the
time is ripe and when you will disclose your program to all?
I sure hope that is the case. As for me I am going fishing before I
replace this computor thing.
Have fun.

Richard Clark wrote:
"To simplify his examples and show the error of the addition consider:
0dBm + 0dBm = 3 dBm"

Yes, that`s right.

0 dbm is a power of 1 milliwatt.
Add another 0 dbm in-phase signal of the same frequency to the first and the total power is 2 milliwatts.
Doubling the power for practical purposes is an increase of 3 db over the 0 dbm level. The combined power is +3 dbm.

I`ve already posted the two ways to make this happen. One way is to cut the load impedance in half while keeping the voltage the same. That is what the power company is doing when the current demand doubles. When the voltage is fixed, doubling the current doubles the power.

The second way is to double the voltage and keep the current the same (double the load resistance for example).

0 dbm is not necessarily 0.775 volts in 600 ohms. 0 dbm is specified as a reference at many different impedances. Correction tables are published for use of 600-ohm db meters at other impedances. The standard is the power, not the voltage.

Best regards, Richard Harroison, KB5WZI

The Lenkurt Demodulator is an award winner for its clarity. I`ll quote from the September 1963 edition:
"Per channel power (in an analog carrier system) is normally stated in dbm. Because dbm is a logarithmic value, two powers expressed in dbm cannot be added to obtain to obtain the total power. Instead, each channel power must be converted to watts, added, and the total then reconverted to dbm.

Marvin,
Sounds like a 'G5RV' that needs to be higher, and
no, wrapping the ladder line around a pole is not the
greatest idea. I think I would read up a bit on the
'G5RV' before going any further with your antenna.

>I had understood I needed a 4:1 balun since my feedline is 450 ohm and the
>coax is 50 ohm. ???

The Impedance that the coax "sees" at the end of the 450 ohm line will almost never be 450 ohms. So a 1:4 impedance transformation isn't necessary. But you probably do need a balun, so a 1:1 current balun is normally used.

Are there any frequencies legally available to hams or citizens that
can carry the required bandwidth? And the cost of such a system would
be prohibitive for most people.

3199. Voltage addition question

Newsgroup: rec.radio.amateur.antenna
Date: 2002-08-17 12:19:55 UTC
From: CAM <Cecil.A.Moore@ieee.org>
Message-ID: <3D5E3F6B.BF90A668@ieee.org>
Source record: 136540

I hope Steve will come back and answer this question but anyone
who understands Steve's approach is welcome to answer. I'm
having difficulty making the voltages consistently add up. For
the following two examples, we are using a signal generator (SG)
equipped with a circulator circuit that dissipates all the reflected
power incident upon the signal generator. Feedlines are lossless.

Here's the earlier example:

100w SG-----50 ohm-----+-----1/2WL 150 ohm-------50 ohm load
100w forward 133.33w forward 100w dissipated
0w reflected 33.33w reflected
(8.33w re-reflected per Steve)

Steve says 75w of the 100w being generated makes it through the
50/150 junction and equals 106.066 volts. He says the 8.33w of
re-reflected power equals 35.355 volts. He adds those two
voltages to obtain the total forward voltage of 141.4 volts.
These voltages do seem to add up.

New example:

100w SG-----50 ohm-----+-----1/4WL 150 ohm-------50 ohm load
100w forward 100w forward 75w dissipated
25w reflected 25w reflected
(6.25w re-reflected per Steve)

The same 75w of the 100w being generated makes it through the
50/150 junction and equals 106.066 volts. The new re-reflected
power of 6.25w equals 30.62v. We know the forward voltage is
122.47v. These voltages don't seem to add up. Anyone know why?

As long as you don't allow the waves to get within about 6 inches
of each other. I hang my ladder-line, accordian-style, from the
eave of my house.

> (2) If you can't roll it up, Can you put a few loops in it if you keep

As long as each turn is kept about 6 inches away from any other turn.
Why do you need to roll it up?

> (3) What is an OK way to secure it to wood framing? A staple or tack
> in the middle of the plastic?

How about: drill and thread the hole in the wood and use nylon screws?
Small tacks shouldn't have much effect.

Wrap about ten turns around the pole (spacing about the same as the ladder line spacing - an inch or so) and it should act as a current balun for you. You may not need a separate balun to connect to the coax. Try more turns if you get excessive common mode current.

Isn't the issue the wind load of the verticals? The tower seems straightforward.

The irony of all this is that its even an issue this OM has to address. After all, how many home TV reception towers are out there in that neck of the woods? Do they have to undergo the same scrutiny?(Not a rhetorical question: do hams have to meet a different, harder, standard?)

3208. Tutorial #2

Newsgroup: rec.radio.amateur.antenna
Date: 2002-08-17 14:52:40 UTC
From: aunwin@fgi.net
Message-ID: <c4becf19.0208170652.79737773@posting.google.com>
Source record: 136549

For those who have followed the Unwin antenna threads(combination loop/dipole antenna) starting with" stagnating antennas, and have not been deterred by technical jargon and also have avoided looking for something complex ,it can now be seen from the drawingd provided, that there is a resemblance to the good old Loop antenna original operating basics.
The ONLY difference is that the small loop that is used to energise the main radiating loop is now replaced by a simple dipole which providess the original function of the smaller loop i.e. the efficient dipole is now the PRIMARY
radiator and the former loop antenna now provides the tuning mechanism.
The final antenna thus supplies much greater gain than either antenna alone.
The combination provides for a much superior radiator than previously known
purely by combining all the best features of the individual antennas and dropping the disadvantages by the wayside, plus ofcourse the provision for collinear gains. Now many will quickly jump to scaling techniques for 7 thru 14 and 3 thru 7 Mhz, which is fine, while I have to stay true to my original object to provide an all round or best anttenna that can be used in small areas by the average ham.
When working on the above antenna thru the provided ranges I did a sweep thru
other HF frequencies only to find that other spans of frequency towards what is termed as top band ,were useable. At the same time I could also generate or remove TVI !!!. It is then a small jump to realise that the transmission line was a factor that was now comming into play ,so what was originally termed an 'antenna' had now become a SYSTEM. My original coax length was around 200 feet long with the horizontal portion being buried, and with a little playing around with its length I was able to use the 40 and 80 bands. The final system shown
that directivity obtained by the antenna alone moved slowly fom a directive radiating pattern to an oval shape and then to a circular shape. All well and good. But a peculiar thing happened as I strolled thru these newly available
frequencies. That if a large enough capacitor was used that went beyond the
original anteena requirements I was still able to supply a modicom of frequency shift. At this point I may add, I had progressed to a 3 elemnt array.
So it appears that the antenna system changes to what appears to be a top driven vertical aided by a variable(very fine) capacity hat!

I have now achieved what I set out to do, a all round antenna that can be used on small lots, rotatable, frequency variable, high efficiancy with measurable gain over other antennas known today.
I will leave it to others to determine if the above aproach can be used update the old wire antennas in the ARRL so theirain a rejuvenated life.
I would caution those who literally swallow the technical explanation that I have given with respect to this antenna and I will leave that the the experts
to explain in detail. For myself as an ordinary run of the mill ham it is enough for me to say that it works and meets my original goal in a grand and unexpected way. Now I am going to buy a lottery ticket

It is work in progress but I am showing it anyway to fill in some gaps relating to my struggles. To those who gave wise suggestions as to what I should have done I thank you for your comments. As you can see I met with many challenges that I was not able to foresee as a layman and I made many mistakes along the way.

3209. Air-Wound Balun Design Info??

Newsgroup: rec.radio.amateur.antenna
Date: 2002-08-17 14:57:12 UTC
From: kelly@dvol.com
Message-ID: <d22b54c3.0208170657.11372751@posting.google.com>
Source record: 136550

Many years ago I had a Heath air-wound 1:1 balun attached to the boom
of my 20m Hy-Gain 204BA yagi which fed the Beta match. The Heath
enclosure was huge, about 10 x 10 x 4, the bifilar wound coils were
maybe 3 inches in diameter and could handle mutiple kilowattts over
the entire HF spectrum as I recall. Looked like they were custom-wound
by B&W. The antenna worked quite well. It seems to me I could wind a
balun with enameled copper wire around maybe 1 inch PVC pipe as a much
more compact "QRP version" of the Heath balun.
>
>
Questions: Do air-wound baluns inherently have lower losses than
ferrite core baluns particularly under high SWR conditions? Over what
bandwidths? Does anyone have a source for design info for homebrewed
1:1 and 4:1 air-wound baluns?
>

Hi George

I sure hope you didn't leave out the most import installation procedure that should be utilized by all CBers.

We refer to this installation as the 'Band Cleaner' as it removes undesirable modulated signals and unwanted RF from the airwaves.

The installation procedure is simple and can be easily followed by anyone capable of pressing a mike key.

The required primary component can be readily found in most households, or it can be purchased quite cheaply almost anywhere.

Simple objects often create desirable results when nothing else is available. Take for example a cat's whisker and a razor blade, they can be utilized as a tuner for broadcast reception.

This device is just that simple and works flawlessly in most cases.

A common ordinary straight pin of any type, or even an opened safety pin will suffice for this 'band cleaning' installation.

The procedure is simple also, the pin is placed anywhere along the coaxial cable that is conveniently accessable to the installer. It is most desireable that the pin be installed such that it passes through the center of the coax and exits the other side of the casing.

The ends may then be clipped off with a pair of side-cutters as close as possible to the cable casing. A little dab of silicone over the clipped pin will prevent moisture from getting into the coax and keep the 'Band Cleaner' device from deteriorating due to weather.

This is a "MUST HAVE" device, that no CBer should ever be without!

TTUL
Gary

Hi

I have access to 25 acres and want to erect the "ultimate" 160/80 directional antenna - either something physically rotatable or a phased array of wires trapsed around. Space not a problem and I have quite a few trees dotted about to use if need be.

I've considered buying four verticals and phasing them with one of those switch boxes (can you do a similar thing with horizontal antennae?). Ground systems would not be a problem. Have also seen those loops and beverage antennas.

What could you reccommend please for the ultimate?

73's.

Cam, W5DXP wrote:
"Is adding power the same thing as superposition?"

Superposition says: When a linear circuit is driven by several sources, the total response can be found by finding the individual response to each source separately and then algebraically combining them.

The sources can include different frequencies and d-c too. This thread has largely concerned combining sources of the same frequency.

The superposition principle works for the electric power company, so that`s the short answer to Cecil`s question.

I have only used the word "superposition" in this thread, so far, in quoting another`s posting. I gave an example using batteries connected in series aiding in response to a query about two transmitters with their outputs connected together. The question was: where does the power go?

With superposition, you short out all of the energy sources, except one at a time, and consider circuit response to that particular energy source. Total response comes from adding individual responses together. This means there is a voltage across a resistance in a circuit which is the sum of the voltage drops produced by the various currents produced by the vartious sources, Ohm says the power in this particular resistance is I squared R or E squared over R.

So, power is derived from superposition as are voltage and current. Ohm is not violated. Power from one source adds to or subtracts from power supplied from other sources. Proof is in the application or removal of other sources. The change can be monitored in the heat produced by the resistor. Remember some of these sources can be d-c as well as a-c with no violation of superposition.

Best regards, Richard Harrison, KB5WZI

Hi Art

I missed the first part of the topic, so what I have to say will probably not be relevent. However, I have seen some fantastic new metals being produced that could at some time in the future be a real boon to how antennas operate.

I entered the hobby at a very young age, little to no money to spend, and even less knowledge about how to properly construct an antenna.

Needless to say, I did the unthinkable and installed dipoles for each band of HF operation all terminating on a connection block of my own design. To this the coaxial cable was affixed and I was on the air. A little trimming here and there and the SWR was almost flat across each band I was allowed to operate on.
If I had 5 bucks invested in my antenna, it would have been a miracle. Yet I quickly earned my WAS and several other awards.

As I aged and learned a little more about antennas, I made the changes that were obvious from what I was studying at the time.
The result of the changes was an antenna system that did not function as well as my original make-shift system, and trying to restore it to exactly the way it was originally set up turned out to be impossible. As once I fixed it, returning it to the original, caused all the problems that the original installation should have had, to appear.

That was 3 decades ago, yet I still try various things from time to time. On occassion, something will work perfectly for me, yet is rarely duplicateable by others with the same results. There are just so many factors related to the area where my antenna is situated that falls into play.

About 6 years ago I was working in a building that was constructed entirely of steel. Needless to say, my little HT would not get out of this massive SHIELD. I was up on the roof and noticed a rubber plug that was used to fill a hole where something used to exit the building. We just happen to have plenty of music wire in the shop, so I grabbed a piece and drove it through the rubber plug. A little math and I cut the antenna to about 1/4 inch longer than it should be for 2-meters, figuring I would have to trim some more off, if it worked. Inside at the ceiling I affixed the shield of the coax to the metal roof by sliding it under the steel plating and the ceiling joist and just wrapped the center conductor several times around the music where where it protruded from the rubber plug.
I had all intentions of making it permanent and adjusting the SWR after I gave it a test to see if it would work at all.

But it was Friday afternoon and time to leave work, so it was left with the coax just running down a support column to the shop.
When I arrived for work Monday morning, the inside of the shop, ceiling and all walls, was covered with some type of spray insulation foam. On Tuesday, a company was there installing drop ceiling track and by the end of the week, the ceiling was covered with heavy 5/8 inch thick fireproof panels, so there was no way I could get back at my antenna connection. I just let the coax dangle by the post for at least three weeks before I finally had the opportunity to see if it would work at all.

So on Friday I brought a little BNC connector and SWR meter, affixed the BNC to the coax and placed the SWR meter in-line. At first I thought my radio was not working because the SWR meter did not register anything at all. However, I heard the Repeater, so I rekeyed and IDed myself. One of the regulars came back to me, expecting me to be in my car. Their first statement was, you can turn your power down a little. OK, save batteries, but I was already on the lower 150MW setting, not on the 5 watt setting. The Repeater was like 20 miles away.
I used this antenna, without any adjustments for the 4 years I worked at this company, never once turning my HT above 150MW. Yet in my vehicle, to reach the repeater at all, I had to be at 25 watts, and to be full quieting had to kick it up to 50 watts and occasionally up to 100 watts, depending upon where I was parked in the parking lot.

On the 150MW setting, I could bring up Repeaters, some of which were 150 miles away and by kicking the little HT up to 5 watts, the receiving station could actually make out what I was saying. Albeit I was mostly covered with noise.
Shortly before I left the employ of that company, I brought in a mobile rig with 5 watt and 25 watt settings, that I used on my breaks and lunch hour. On the lowest 5 watt setting, I was continually asked to reduce my power, as I was bringing up neighboring Repeaters on the same repeater pair. It became necessary to go back to my 150MW HT to prevent this problem.

Although the coax has now been cut off at the ceiling, the little music wire was still sticking out of the rubber plug on the roof the last time I visited the place of my former employ some 6 years after the fact.

What is it that made this antenna outperform anything else?
Location, Height, distance between vertical and shield, or some other unknown factor we are not yet aware of?

I have tried to duplicate this effect by carefully reconstructing the simple antenna using the same type music wire and even the same brand and size of rubber plug on another steel building. However, in all attempts, a simple mag mount mobile would outperform the wire in the plug method.
So my determination is, there was something special about either the building itself, it's location, the placement of the antenna, or the

way it was connected to the coax. Perhaps even the foam insulation was a contributing factor. I don't know since I did not test it prior to the foam or ceiling being installed.
Many fellow club members came by to visit while I was working for that company, bringing their own HTs and connecting them to the antenna, and obtaining the same magnificant results. It was the talk of the group for more than a year. Their determination was it was exclusively due to the location and size of the building. Yet a mag mount placed on top of this same building, within a foot or two of the old antenna in any location did not produce any enhanced results.

So, just like my nickel plated yagi that wouldn't work, there are many things about antenna's we still do not know.

Cecil,

Your answer exhibits a major factor in the disagreement over these matters. Almost everyone starts with assumptions that include lossless, isolated-system, steady-state, and so on. In many cases, however, these assumed conditions actually confuse rather than simplify.

A classic paradox problem in elementary circuit theory is a simple capacitor problem.

SETUP

Start with single capacitor with capacitance "C", charge "Q1", and Voltage "V1". The energy stored in the capacitor is "W1".

The descriptive equations are:

Q1 = C * V1, and

W1 = 1/2 C * (V1)^2

Now add an identical, but uncharged, capacitor in parallel with the first. This is done by a simple wire and switch arrangement.

IMPORTANT ASSUMPTIONS

Assume all circuit elements are ideal. Everything is lossless, and there is no inductance in the wire. The capacitors do not interact directly, and there are no interactions with anything else in the world

QUESTION

What is the final configuration in terms of charge, voltage, and energy.

ANSWER

Charge is conserved, and it is shared equally between the capacitors. The final charge on each capacitor, Q2, is 1/2 Q1.

Voltage is equal in the two capacitors, and it is 1/2 of the initial value in the first capacitor, since V is proportional to Q. Therefore V2 = 1/2 V1.

Energy is still 1/2 C * V^2 in each capacitor, or in terms of the final variables,

W2 = 2 * 1/2 C * (V2)^2 = 1/2 * 1/2 C * (V1)^2 = 1/2 W1

WHAT'S UP???

Since we like to believe in conservation of energy, and we generally
believe in these elementary expressions for the basic characteristics of
capacitors, there is something wrong.

What is wrong is that our initial assumptions about the problem are
impossible to achieve. If the system is really lossless then it never
comes to static equilibrium after the switch is thrown. If there is any
loss then the system undergoes damped oscillation until the excess
energy is lost as heat.

Many of the examples of the nature, "add 100 W to 100 W" suffer the same
problem. You simply cannot make all the ideal assumptions and also
require that the *readily observable energy* is held constant throughout
the problem.

You may try to assume an ideal system, but Mother Nature won't always
let you get away with it.

> the total power is 2 milliwatts.
> Doubling the power for practical purposes is an increase of 3 db over
> the 0 dbm level. The combined power is +3 dbm.

Let me try this again

The addition of log terms is the same as the multiplying of equivalent
non-log terms. So
3 dBm + 3 dB = 6 dBm
is the same as
2 mw * 2 = 4 mw
Any dB term has no units, it's just a numerical value.

The subtraction of log terms is the same as the dividing of equivalent
non-log terms. So
3 dBm - 3 dBm = 0 dB
is the same as
2 mw / 2 mw = 1
The dB term has no units since they (the units) cancel in the
division.

Now
0dBm + 0dBm
would be the same as
1 mw * 1 mw
which is 1 square milliwatt or 1 mw^2. The units must be carried along
in the conversion.

So if you really wanted to write such an equation,
0dBm + 0dBm = 0 dB(smW), where dB(smW) is dB relative to a square
milliwatt

Please explain again how 0dBm + 0dBm = 3 dBm. Explain what the
physical significance of 1 square milliwatt would be.

> I`ve already posted the two ways to make this happen. One way is to cut
> the load impedance in half while keeping the voltage the same. That is
> what the power company is doing when the current demand doubles. When

> the voltage is fixed, doubling the current doubles the power.

I remember enough from my power course years ago to bet that the power company doesn't just throw a switch to bring one generator on-line with another. I would bet they carefully match the power factor (the phase angle between voltage and current) of one generator to the power factor of the other. In other words, they add the in-phase voltages and currents.

Sounds big, but that's only a bit over a quarter-wave high
on 160 meters, which is the more important of the two
bands cited!

About the same as a 20 meter yagi at 20 feet, or a 40 meter
antenna at 40 feet!

Not "Ultimate", for sure!

Put that rotatable full-sized 3-element 160m yagi between 250-
and 520-feet (half to full wavelength) up on 160 meters.

From a practical point-of-view, a pair of quarter-wave high 4-squares
is a better choice if you need to change directions.

My degree is in power engineering and I don't recall a power company ever adding generators in series because that would lift the ground of one generator up to the generator voltage of the other. It might even be illegal to do so. All of the automatic reclosure circuitry with which I am familiar puts (almost) equal voltages in parallel allowing the two currents to be whatever they need to be to satisfy Ohm's law. Of course, my knowledge of power engineering is 40+ years old but I guarantee you they don't double the voltage and double the current at the same time unless they switch in 300% more power generation capacity. 100MW + 300MW = 400MW

Hi David,

See what I did in my backyard:
http://www.astrosurf.com/lombry/qsl-longwire.htm

The longwire of about 40m is tied at about 3m high only. It is made of simple electric wire + coax directly connected to my RTX (could be best !).

The built-in antenna tuner of my RTX do the rest to SWR near 1:1 in quasi all bands including WARC.

Work fine as in 2 months I heard nearly 170 DXCC in all HF bands from canada to Argentina, Antarctica or South Africa to Finland and Taiwan to New Zealand !

(ok the QTH seems QRO: this is in a small village at 7 km from any city, 200m on top of "hills"), no one building or QRM source around. QRM is weak about S-2/3 on all band (S <1 on 28 Mhz).

In cannot say the same for my QTH in LX where my 15m sloper +10m of wire in the appartment capture much QRM, at least 2-3 points above vs the first QTH. I bough an MFJ-1026 noise canceller for this last.

However, as OM you are and as you have 150' available, I suggest you warmly (strongly) to erect a multiband dipole type G5RV at about 10m high attached between two masts or in a tree and to your chemny. Results must be better, and surely for emission.

Hope this help !

Source record: 136473

Hi,

Pfff.. I'm trying to find on the place dealers or manufacturers or HF loop antennas as my blooming (short)longwire creates severe QRM in my LX QTH.

But browsing the web I only find 2 manufacturers : MFJ and another one + AEA (www.ryl.nl) but his isoloop seems discontinued.

So roughly there is only one available, the two models from MFJ...

Is this design so bad that no other manufacturer wants to sale such antennas?
Surely not.

So where can I find other loops ?

Thanks for comments.

Thierry

Which you will be the first to admit that you have neither modeled,
had modeled, measured nor independently compared in controlled
situations and follows from a history of similar claims later shown to
be overstated. But the gall is to expect and demand someone else to
tote your water:
> I will leave it to others to determine if the above aproach can be
>used update the old wire antennas in the ARRL so theirain a
>rejuvenated life.
>I will leave that the the experts to explain in detail.
Where you condemn working theory as regurgitation, dismiss critics as
stupid, ignore tepid results, and whine on about how lazy those who do
not step up to prove your claims must be. Your recruitment of help is
seriously undercut by your backhanded thanks.

Art, you should be proud you've designed an all band antenna that at
least does not lose anything along the way. This is no trivial task
and is the shimmering nirvana of fractal builders. It is sufficient
that it exhibits characteristics of a dipole/beam with a novel (or at
least handy) method of tuning.

Fluidmotion with their SteppIR is doing just this and they have no
problem attracting customers to their booth to purchase simple beams
of modest specification at more than ambitious prices. None of them
signed on here to ask for peer review either. Enquiries to their
product here have been occasional but from apparently committed
buyers. Testimonials from customers have been few, but positive.

However, let me add some perspective to this;
by their own specs, their antenna offers
"8.8 Average Gain, Forward dBi (free space)"
and their claim is
"Gain that equals or exceeds that of
antennas on much larger booms!"

A simple comparison to the NBS Yagi reveals more gain at 9.68dBi (free space). But, hey! Who is going to quibble less than a dB difference? (Hardly the loser.) Similarly, who is going to withhold a chuckle over their claim? Even then, there among the smiling is at least one fellow opening his wallet. In the arts (I do more than weather) this characteristic of the audience is known as "the willing suspension of disbelief."

I'd start by looking up Comtek. Jim Miller makes four square controllers and
they work well on 80m, I don't know if he's ever done one for 160m.

Good luck, you're really blessed with all that space!

A very interesting story. But I seriously doubt that the performance of this antenna was due to anything about antennas we don't know. The fact is, there was something about this particular antenna you don't know. A first guess would be that it was coincidentally placed in a spot where signals from several paths happened to add in phase from one particular repeater -- not exactly an unknown phenomenon. Anyone with a VHF mobile setup has observed this.

Just because we don't understand how a particular antenna works doesn't mean there's some mysterious process that's yet to be understood. A Brazilian tribal rain forest dweller wouldn't understand how a light switch works. That doesn't mean that "there are things about light switches we still do not know." Unless, of course, "we" is limited to tribal rain forest dwellers.

Source record: 136478

Food for thought: Superposition

Superposition is a simple concept, but like other simple concepts, it can be and often is misapplied.

The test for superposition is as follows:

If excitation x1(t) produces response f(x1(t)) and x2(t) produces response f(x1(t)), then x1(t) + x2(t) produce f(x1(t) + x2(t)).

Let's take a simple example. Connect a 50 volt DC voltage source (V1) in series with a 30 volt DC voltage source (V2) (+ to -), and this in series with a 20 ohm resistor (R) to make a simple loop. We know that I = V/R, so we can say:

I = f(x) = x/20 ohms
V1 = x1 = 50 volts
V2 = x2 = 30 volts

Let's see if the voltages and currents can be superposed. Mathematically,

I1 = f(50 volts) = 50 volts/20 ohms = 2.5 amperes
I2 = f(30 volts) = 30 volts/20 ohms = 1.5 amperes
f(50 + 30 volts) = (50 volts + 30 volts) / 20 ohms = 4 amperes = 2.5 + 1.5

So the voltages satisfy the requirement. In our circuit, we can do this test by turning off all the sources (replacing them with short circuits, since the impedance of a voltage source is zero), then turning them on one at a time. With only V1 on, I = I1 = 50/20 = 2.5 amps. With only V2 on, I = I2 = 30/20 = 1.5 amps. With both on, I = (50 + 30)/20 = 80/20 = 4 amps. This is the sum of the currents we got from each source by itself.

We can turn the 30 volt source around the other way so it subtracts from the 50 volt source, and still have superposition satisfied. In that case,

I1 = 50/20 = 2.5 amperes
I2 = -30/20 = -1.5 amperes
I1 + I2 = (50 - 30) / 20 = 1 ampere

The conditions for superposition are pretty strict. For example, we can't have a source that's one value when we turn it on one time and another value when we turn it on another time. And we can't have a voltage or current source whose value changes depending on the load. But we can have time varying sources like sine waves, providing the voltage-time function they produce stays the constant. And we can have, say, a source with 50 ohm impedance. Just replace a source with a box containing a voltage source in series with a 50 ohm resistor. Turn the

source off and on as before, and you'll see that superposition is still satisfied -- all we've done is add a resistor to the circuit. And even a simple function like the familiar first order linear equation f(x) = mx + b doesn't satisfy superposition.

Let's see if the powers produced by the sources can be superposed. Turning the 30 volt source back around so its voltage adds to the 50 volt source, we define the function relating power to voltage.

P = f(x) = x^2/20 ohms
V1 = x1(t) = 50 volts
V2 = x2(t) = 30 volts

Test for superposition:

P1 = f(50 volts) = 50^2/20 = 125 watts
P2 = f(30 volts) = 50^2/30 = 83.33 watts
f(50 + 30 volts) = (50 + 30)^2/20 = 320 watts.

f(50 + 30) isn't equal to f(50) + f(30), so this function (power) doesn't satisfy superposition. We can see this with the circuit by turning each source on in turn and observing the power dissipated by the resistor, then turning both on at the same time and looking at the power.

The test for superposition is simple, so before declaring that superposition holds for a particular quantity or circuit, first plug the values into the test and see if what you say is true.

Cecil, it seems to me you are missing the point concerning how complementary
reflections
establish either a short or open circuit to reflected waves, as I have
discussed in Chapter 23 of
Reflections and in QEX Mar/Apr 1998. Whether you call these circuits real or
virtual is
irrelevant here.

Let's assume your 1 volt wave at 90 degrees and the 1 volt wave at -30
degrees superpose at an
intended matching point, with their resultant at +30 degrees, as you stated.
Let's also assume the
matching point is at the input of an antenna tuner. We know that when the
tuner is adjusted to
provide a match the input impedance will be 50+j0. However, with the
resultant at +30 degrees
the input impedance will be some value R+jX, indicating that some reflected
waves are
penetrating the match point, resulting in a less than perfect match. In
other words, the tuner is

mistuned--when re-adjusted to obtain a 50+j0 input impedance the resultant voltage angle will
be either zero or 180 degrees, depending on whether the resulting impedance to the reflected
waves is an open or short circuit, respectively.

However, if you review my references above you will note that to establish a short or open
circuit to reflected waves the two sets of reflected waves that superpose to establish the short or
open circuit must be complementary. That is, to establish the short circuit the voltages of the
two reflected waves must be of exactly the same amplitude, but with opposite phase angle. To
establish the open circuit the respective currents must be of the same amplitude, but with
opposite phase angle. If the resultant angle of the voltages is 180 degrees the current resultant
angle will be zero and the impedance to reflected waves is zero--a short circuit only to reflected
waves--50+j0 to the source waves. Conversely, if the resultant angle of current is 180 degrees
the voltage resultant angle will be zero degrees, and the impedance to reflected waves is
infinite--an open circuit only to reflected waves--50+j0 to the source waves.

Consider the case where the voltages are equal and of opposite polarity. Analytically these
voltages can be delivered by two separate generators at the matching point. When the voltages
from these generators are equal and of opposite polarity a short circuit is established, just as
surely as if two batteries of equal voltage were connected plus-to-minus and plus-to-minus.

Now consider the energy contained in the reflected voltages and currents from the viewpoint of
their corresponding electric and magnetic fields. We know that the electromagnetic field
contains an equal amount of electric and magnetic fields, with their energies alternating
cyclically between them. According to Poynting's theorem, when electric and magnetic fields
encounter a short circuit the electric field collapses and its energy is transferred into the
magnetic field, causing it to double. Simultaneously, the voltage goes to zero and the current
doubles. However, as the energy in the doubled magnetic field continues changing, half of its
energy is re-transferred back into a new electric field with its direction

reversed. The magnetic
field returns to its original value with its direction also reversed, thus establishing a total re-
reflection of the energies in the fields of the former reflected waves.

At this point the re-reflected electric and magnetic fields merge with the corresponding fields of
the incoming electromagnetic field from the source. Thus, contrary to Steve's position that the
reflected and source voltages add to establish the forward voltage, and ultimately the forward
power, it is the energies in the fields that add as the source and re-reflected fields merge. The
true forward voltage in the steady state determined by multiplying the source voltage by the
square root of the power increase factor, which is 1/(1-rho squared), where rho is the voltage
reflection coefficient of the load mismatch on a lossless line. Steve asserts that the forward
voltage is derived from Johnson's Eq 4.23 on Page 100. However, Steve's problem is that he
fails to understand that this equation derives the voltage of the standing wave at any point along
the line, not the forward voltage, which is constant along lossless line.

It is universally known that when an electromagnetic field encounters a short circuit, the result
is total reflection of both voltage and current. It is still a mystery to my why there is so much
confusion about this subject.

> Bill N3WK

Bill, I understand the -gamma and +gamma as E- and E+ respectively, but it
is the addition of E- and E+ at points generally along the line that add at
each point to establish the standing wave. Steve says it establishes the
forward voltage, which is not correct.

The forward voltage is determined by multiplying the source voltage by the
square root of the forward-power increase factor, which is 1/(1 - rho
squared), where rho is the voltage reflection coefficient of the mismatch
terminating a lossless line.

Food for thought: Source reflections

Here's an insight that might help you understand forward and reflected waves a little better.

Consider a transmission line at the moment a signal is first applied. A wave will travel down the line, with voltage and current related by Vf/If = Z0. The wave hits the end of the line, and some fraction of it will be reflected. This fraction, which can also include a phase shift, is the reflection coefficient GAMMA at the end of the line. (Lower case rho is also sometimes used for the complex reflection coefficient, but it's also sometimes used for the magnitude only.) The reflection coefficient at the end of the line is determined solely by the load impedance Zl and the line's characteristic impedance Z0: GAMMA = (Zl-Z0)/(Zl+Z0). It's a simple relationship, but you have to remember that Zl can be complex and, if the line has loss, Z0 can also be complex.

If Zl isn't equal to Z0, GAMMA won't be zero, and GAMMA times the forward wave is reflected at the end of the line and travels back toward the source as a reflected wave. When it reaches the input end of the line, we've established standing waves along the line due to the interference between the forward and reverse waves. The SWR is, in fact, (1 + rho)/(1 - rho), where rho is the magnitude of the reflection coefficient GAMMA. We can also calculate an impedance V/I at any place along the line.

If the source impedance isn't the same as the line impedance, some fraction of the reverse travelling wave will be re-reflected toward the source. And now we come to the important point that I believe people often don't think about. Whatever fraction of the reverse wave is re-reflected back toward the load, GAMMA times that amount will be reflected back toward the source when it reaches the load end. So this re-reflection adds some amount (depending on the source mismatch) to the initial forward wave, and GAMMA times that amount to the reverse travelling wave. It changes both the forward and reverse travelling waves in the same proportion as the original pair of waves! So THE RATIO OF THE FORWARD AND REVERSE TRAVELLING WAVES ISN'T CHANGED BY THE REFLECTION FROM THE SOURCE. The amplitude and perhaps phase of the forward and reverse travelling waves change as re-reflections continue to occur until steady state is reached. BUT THE RATIO OF THE FORWARD AND REVERSE TRAVELLNG WAVES STAYS THE SAME AS IT WAS BEFORE ANY RE-REFLECTIONS TOOK PLACE FROM THE SOURCE. THE SOURCE MISMATCH HAS NO EFFECT ON THE RATIO OF FORWARD AND REVERSE WAVES. Therefore, the source mismatch has nothing to do with the SWR. This is something that hopefully most people know, but too many people attribute too much

importance to the source match.

If we change the source match, the magnitude and phase of the source reflections change, altering the magnitude and phase of the forward and reverse travelling waves. In other words, we're adjusting the amount of voltage and current (and therefore power) we're putting into the line. But we're not changing the SWR or the ratio of the forward and reverse travelling waves. That's determined solely by the load impedance and line Z0.

3243. New tower = many questions

Newsgroup: rec.radio.amateur.antenna
Date: 2002-08-17 21:23:27 UTC
From: JWheeler <kd5bcu@yahoo.com>
Message-ID: <ultflvos7ioe14@corp.supernews.com>
Source record: 136484

I have just become the proud new owner of about 70 feet of Rohn 45. The reason I have this new tower is that a tornado blew it over. It was the property of my local club until said tornado came through a couple of years ago and nicely deposited most of it in a stand of pine trees. There is remained until a few weeks ago. It started out as about 190 feet, but only about 150 of those could be salvaged. Another member of the club and I, being the only current club members needing towers, divided up the salvaged sections. I hope, in the next few weeks, to host a tower raising party. Before that time comes, I need to do a good deal of research. I am pretty sure there are a good number of experts who frequent this forum (good amateurs are welcome, too). All of the basic nightmares have started coming to mind now that I have it sitting in the backyard. What if it falls!!! Ok, none of that. I want to be sure to over compensate when this thing goes in. I am going to have a custom tilt-over base made since I have a friend/fellow ham who works for a local utility company and can call in a few favors with the guys at the machine shop. Why spend mega-bucks when you can have a better-than-retail version built on the cheap (maybe even free)? Right?
At any rate:
1. What do I need to look at to make sure this thing stays up until I'm ready for it to come down?
a. What dimensions do I need to start with on the hole? Ball park estimates are okay. I plan to go bigger than the average suggestions just to be sure.
b. What are some good suggestions on types of material for this custom base plate?
c. At 70 feet, does this thing need to be guyed? Please say no... my wife won't be happy if she has to look at my ugly (her words) tower AND deal with the presence of guy wires in her yard.
d. What's the easiest way to stand one of these things up?
z. What have I missed? .

I know that windload is going to be an issue. I currently have a 10 element 2 meter beam, but may add a 2nd beam to have a stacked array. I may also decide to part with both beams and opt instead for an array of stacked 4 element quads. My current HF antenna is the standard inverted-V, but I hope in the near future to add a triband beam to the mix. I will also anchor one corner of an 80 meter full wave loop on a leg of the tower. If possible, I'm going to erect this thing far enough away from the house that, if it does fall, it won't land on any structure, but as stated above, I want to be sure it won't fall from anything short of direct intervention from God.
I live in East Texas, where thunderstorms are not uncommon. High winds often accompany these storms. Then, there is the occasional tornado, such

as the one I have to thank (?) for my new tower. To the naked eye, these tower sections are in remarkable condition knowing what they have gone through. I look forward to any and all advice.

Thanks in advance,

JWheeler
KC5AV

I'm sure I've taken an ultra-simple look at this, so be gentle

Some loop antennas are described in ham books from ARRL, RSGB and in ham magazines. If you want you may contact me (even in french).

JW....

Your planning on a REAL disaster, for sure. A Rohn 45 is not a small tower and the only way you can install it safely is by knowing exactly what you are doing!!!! You want it to survive strong winds; you want it to survive a tornado, yet you do not want to put guy wires on it!!!

Two things I suggest you do BEFORE you consider doing anything with those tower sections. One is to go to www.contesting.com and look in the TowerTalk reflector, read back for several months everything you can about the Rohn 45, THEN put these same questions to that very knowledgale group. Then, do not take their answers as gospil, go to the Rohn web site and read their published information on the Rohn 45.

The main point about putting up a tower is YOU NEVER DO ANYTHING EXCEPT INSTALL IT EXACTLY THE WAY THE MANUFACTURER SPECIFIES!!! Tower manufacturers had professional engineers design these things and us AMATEUR's do not know how to do it better than those engineers do. Don't go 'cheap' or one day your going to have it laying on top of your house.

Be safe, do a good job, and then enjoy your tower for a long time.

73,
Tom/W4BQF

Food for thought: Instantaneous and average power

Power is the rate of doing work, or expending or transferring energy. Because these quantities can vary with time, power can also be a function of time. If power is used to express movement of energy (such as the power in a radiated field), a direction can also be assigned to it.

In terms of voltage and current, power is simply calculated as:

P(t) = v(t) * i(t)

where v(t) and i(t) can be any arbitrary functions of time.

We're often interested in the steady state case, where v(t) and i(t) are sine waves of the same frequency. In that case, we can represent v(t) and i(t) as:

v(t) = V * cos(omega*t + phiv)
i(t) = I * cos(omega*t + phii)

where

V = the peak (not RMS) value of the voltage
I = the peak (not RMS) value of the current
omega = 2 * pi * frequency
t = time
phiv = phase angle of the voltage
phii = phase angle of the current

Multiplying to get power,

P = V * I * cos(omega*t + phiv) * cos(omega*t + phii)

Using the trig identity

cos(a) * cos(b) = 1/2[cos(a-b) + cos(a+b)]

the power equation can be rewritten

P = (V * I)/2 * [cos(phiv - phii) + cos (2 * omega * t + phii + phiv)]

It's evident that this is the sum of two quantities,

(V * I)/2 * cos(phiv - phii), and
(V * I)/2 * cos(2 * omega * t * phii + phiv)

The first term is a constant value that doesn't vary with time. The second is a sine wave, with frequency equal to twice the frequency of v or i. So the power does change with time. If we graph it, we'll see a

sine wave (the second term above) with frequency of twice that of v or i, with an offset equal to the first term above.

Let's look at some interesting cases. If v and i are in phase, phiv - phii = 0, and the offset (the first term above) will be equal to (V * I) / 2. This will bring the entire waveform above the horizontal axis, so the power will never be negative. The power will touch zero just for an instant at the most negative part of each cycle.

If v and i are 90 degrees out of phase (it doesn't matter whether the difference is + or - 90 degrees, since cos(-x) = cos(x)), the first term will be zero. The power waveform will then be a sine wave centered around zero, and will be positive for half of each cycle, and negative for the other half. I'll talk about what this means in a moment.

If v and i are between 0 and +/-90 degrees, the first term will be positive, but not enough to bring the whole power waveform above zero. So it will be positive for most of each cycle, but negative for part.

v and i will be in phase if the load is purely resistive. That is, the impedance Z relating v and i (Z = v/i) is purely real. In that case, power always flows toward the load (actually, in the direction defined as positive for I), although its amplitude varies during the cycle.

If Z is a pure reactance like an inductance or capacitance would present, then phiv and phii would be 90 degrees apart. There's still energy flowing in the circuit, but it flows one way for half the cycle and the other way for the other half. In the case of a purely capacitive load, the energy is accumulated and stored in an electric field for half the cycle, then returned during the other half. The same thing happens with a purely inductive load, except the energy is stored in a magnetic field. It's very important to realize that power is moving back and forth in this circuit, even though it's not doing any work. Because it doesn't do work, the power in this situation is sometimes called "imaginary", "reactive", or "VAR" (volt-amp-reactive) power. But it can be calculated, detected, and measured flowing in the circuit just as surely as power that does work.

So how do we find out how much work is being done? The rigorous way is to integrate the power over the period of interest. This works for any power waveform, not just the sinusoidal steady state waveform. But a way that works as well, and amounts to the same thing, is to calculate the average power, which will be a constant value for the steady state condition if calculated over an integral number of cycles. This is multiplied by the time to get the work done or energy expended, or the net energy moved. There's a standard way to calculate the average value of any periodic waveform, and that could be done here. But for the steady state condition, a simple inspection of the two terms making up the power waveform show that the first term IS the average value. The average of the second term is zero, so it contributes nothing to the overall average. So the average power is simply

(V * I)/2 * cos(phiv - phii)

which is equal to

Vrms * Irms * cos(phiv - phii)

Notice that if the load is purely reactive, the average is zero and no work is being done. No work is done by energy that leaves the source then is returned.

Although the average power is useful in determining how much work is done, energy expended, or net energy moved, remember that it doesn't tell the whole story. Keep in mind the statistician who drowned while crossing a creek whose average depth was only three feet.

One final caution: Be careful when using phasor quantities to calculate power. Phasors are not exact representations of the corresponding time waveforms, and ~V * ~I, where ~V and ~I are phasors, is not power or any other useful quantity. Among other problems, phasors have a built in assumption that all quantities have the same frequency or are D.C. So for that reason alone there's no way to express power as a single phasor quantity or single quantity plus a D.C. term as a function of V and/or I, since V and I have different frequencies than P. It does turn out that Re{~V * ~I(conj)}, where ~I(conj) is the complex conjugate of ~I, or Re{~V(conj) * ~I} does happen to be the average power. So it's possible to calculate the average power from phasors, but not to express power as a phasor quantity in the same equation with V or I.

>(1) If you need a little slack, Can you put some waves in it?

Yes. 450 ohm line as well as coax should act like a transmission line. Ideal transmission lines don't radiate, you want the antenna to do that. The reason we go to pains in the routing of 450 ohm line is to try to keep the currents balanced in the line so it will not become part of your radiating antenna. Some antenna systems depend on transmission line radiation. But your question is on routing of ladder line, route it so it won't become unbalanced and radiate. Keep it away from conducting surfaces, and don't coil it so it will couple with itself or anything else.

I put up two Rohn 45s in the Caribbean in 1987 that are still standing
today. 70 footers, on a hill, 4-way guying and loaded top to bottom
with heavy duty CATV antennas. One hurricane carried the 20 foot dishes
about a quarter mile away but did no more than wet the towers.
Base and all 3 guys are about 1 cubic yard of concrete which was a bit
excessive.
Only corrosion is a brown tint on the windward side of them after 15
years.

In this part of the world I wouldn't even consider non-guyed 45 because
of regular hurricanes. If you get 80+ mph winds occasionally you
shouldn't either. Tornadoes don't care...they will take down most
anything.

One comment, I'd mark the sections and sides somehow to facilitate
reassembly. It ain't gonna go back together like factory fresh
sections.

Good luck with convincing the yf that it must be guyed.

Having been in Little League Baseball, I find Charles' attitude the same
as what many parents expect. Their kids who are pitiful players are
worthy of a table full of 'participation' trophies even when they come
in last place. So whats the prize for the real winners?
This "you can be a superstar if you try" crap simply doesn't work when
you try to spread it across different disciplines. Its an insult to the
talented and a false hope to the hopeless.
Anybody who has the ambition to excel in something typically has the
talent to do so or else that ambition is short lived. You can't
legislate it by force-feeding government edicts that make them appear to
be equal.
I'm all for any free-bander who can put together a fine station and work
1000 countries without a bunch of frigging echoes, swingbacks, truck
stop chatter and all that other crap. They become hams quite naturally.
On the other hand, toads like Charles (see his pix) signing names like
"fantastic@sex" pretty much reveal his character as something you don't
want your children to encounter. He approves opening the doors simply
to accumulate a bigger corral for his deviance and you don't have to
guess very far what that might be.

Food for thought: Waves and power

In a transmission line under steady state conditions, we can conveniently separate the voltage and current into forward and reverse travelling voltage and current waves. In actuality, electric and magnetic fields were created when power was first applied to the line, and if both source and load are mismatched, an infinite number of reflections took place from both ends of the line. And arguments can be made that fields themselves are mathematical constructs. But the simplified model of single forward travelling V and I waves and single reverse travelling V and I waves are adequate to explain virtually everything about voltage, current, impedance, and power that can be observed and measured. Hence, the model is well accepted and in general use.

The following discussion will be restricted to steady state analysis with sinusoidal voltages and currents.

The forward and reverse travelling voltage and current waves add at each point along the line. At any point 1 along the line,

```
v1 = fv1 + rv1
i1 = fi1 + ri1
```

where f and r denote forward and reverse waves respectively, and v1, fv1, rv1, i1, fi1, and ri1 are all functions of time (sinusoids). Note that when using the above formula for i1, the positive direction of current is physically the same (toward the load) for both the forward and reverse waves. With this convention, the sign of i changes when it reflects from the end of the line.

At any point along the line, we can calculate a power. We can calculate the power directly from the time functions of voltage and current. In a lossless line with resistive load, this isn't difficult, but it becomes pretty ugly in the general case where the line has loss, and reflection coefficient and line characteristic impedance can be complex. In the general case, it's not too difficult to calculate average power from phasor representations of v and i.

The power at the input of the line, or any point 1 along the line is:

```
p1 = v1 * i1
```

where all three quantities are functions of time.

"Forward" and "reverse" powers are often calculated as follows:

```
fp = fv * fi
rp = rv * -ri
```

The negative sign for ri is because of the common convention that the positive direction for the reverse power is in the direction of flow, i.e., from the load toward the source, while the convention followed for ri is from the source to the load.

Because p = v * i, and v and i are each the sum of a forward and reverse component, we can write that at any point 1,

p1 = (fv1 + rv1) * (fi1 * ri1)

and, expanding,

p1 = fv1 * fi1 + rv1 * ri1 + fv1 * ri1 + rv1 * fv1

A popular concept is to consider the "forward" and "reverse" powers as being waves travelling along with the voltage and current, and the net power being moved at any point being equal to their difference, that is,

p1 = fp1 - rp1

Substituting from equations above,

p1 = fv1 * fi1 - (rv1 * -ri1) = fv1 * fi1 + rv1 * ri1.

Unfortunately, this isn't the same result as we got by directly calculating the power from the total voltage and current at a given point -- two terms are missing. The product of the sum of the waves isn't equal to the sum of the products. The net power isn't the same as the difference between the forward and reverse powers. (Don't blow your stack yet. I said they're not the same, not that they can't be equal or nearly equal. Read on.)

If we measure i and v at the input end of the line and multiply them, the result is the power entering the line. The average value of that power is the net amount of power being delivered to the input end of the line that can do work. (From an earlier discussion, the time power waveform can include power (so-called reactive power) being pushed into the line and being returned each cycle. This power doesn't do work, and doesn't show up as part of the average.) So the actual power being delivered to the line is the power calculated by first summing the forward and reverse voltage and current waves, not the difference between the forward and reverse power. Because we can take the average of each additive term in either expression and add them to get the overall average, the same problem exists for the averages as for the time waveforms themselves.

But directional wattmeters work and give useful results. Why?

The reason is that AS LONG AS THE LINE Z0 IS ENTIRELY REAL (RESISTIVE), THE CROSS TERMS fv1 * ri1 AND rv1 * fv1 ARE EXACTLY THE NEGATIVE OF EACH OTHER AND CANCEL. This happy result occurs because of the unique relationship between the forward and reverse voltage and current waves, and between current and voltage. As long as Z0 is purely real, we can calculate the actual power flow by subtracting the reverse power from the forward power.

What happens when Z0 is complex? The cross terms are then functions of not only the phase of Z0, but also the magnitude and phase of the reflection coefficient, and the length and attenuation of the cable. So the difference between the actual power and the power calculated by subtracting "reverse" from "forward" power depends on all these quantities.

As it turns out, Z0 can be considered to be purely real in the vast majority of amateur antenna situations. Reactive Z0 is caused by high loss per wavelength. As frequency increases, wavelength decreases in inverse proportion to the frequency, but loss per unit length increases only as the square root of frequency. (This is true as long as conductor loss dominates, which is the case for coax cables with decent dielectric up to 1 GHz or higher.) So for a given cable, the loss per wavelength decreases as frequency increases. Consequently, reactive Z0 occurs at low, not high, frequencies, and is more pronounced with lossier cables. At 3.5 MHz, the impedance of RG-58 is about 50.0 - j1.2 ohms. At 1.8 MHz, it's 50.0 - 1.7. It's not likely that this amount of reactance would cause objectionable errors in power calculations. About the most extreme more-or-less practical case would be RG-174 at 1.8 MHz, which has a Z0 of about 50.4 - j5.9 ohms. That might produce a noticeable error when calculating power from forward and reverse, but this isn't a common combination of cable and frequency.

Lofers should take note, though. Below the AM broadcast band, some cables could have a significantly reactive Z0.

Directional wattmeters such as the Bird indirectly calculate the power in an internal line which presumably has a very nearly pure real Z0, so they should remain accurate even if connected lines have complex Z0.

One of my college professors made a statement that stuck with me: "Progress hasn't been set back so much by getting the wrong results with the right methods as it has by getting the right results by the wrong methods." When you subtract reverse power from forward power, be aware that you're not actually calculating the total power. You're just getting close enough for practical purposes. Usually.

This group showed A3 needs choke or balun to keep RF from coming down
the cable..
Most of the beam antenna requires(?) coax choke or balun from their
manual..
But old TA33 does not require any choke or balun on the manual.. Is
there any reason?? or special Mosely design??

I acquired old TA33 form local old man and am hesitating to put coax
choke or balun..
Please let me know..
Thanks
Scott

Permutations of 802.11 at 5GHz, or even 802.11b at 2.45 GHz, but probably need to go to X-Band with a couple Gunnplexers. All ISM bands.

Now, practically, there were some products called Rabbits or some such which did exactly what he wants to do. Put the signal on a UHF channel, I think. And, if so, the FCC made them go away. I have also seen some 913 MHz ISM TV links, but they were low bandwidth, and not broadcast quality.

For the amount of radiation from the outside of a coax feedline connected to the centre of a balanced dipole without a balun at the junction, download program FEEDPOWR in a few seconds and run immediately.

In practical circumstances it may be less than what the old wives lose a lot of sleep about but it certainly does exist.

No Richard, I have modeled it and it shows me that the above
statemnt is apparently correct. Field patterns appear the same also
and the curent curve shows separation and phase correction either side
of the center. The current peaks are higher than normal with center of
area of current curve further away from center as seen with normal
dual curves. But it was I that did the modeling and I am not confident
in modeling, but when built per model it worked as expected with near
impedance valuess

> had modeled, measured nor independently compared in controlled
> situations and follows from a history of similar claims later shown to
> be overstated.
Well a person on this group is going to try to do that in an amateur
format.He is presently indisposed because of family problems and
family always comes first
Controlled situations is a difficult thing for an amateur to do. And
from past experiences it would appear that there is always more
discussion regarding the
controlled circumstances in ham circles than in the antenna itself.
Elswear it seems sufficient to quote model figures and others will say
garbage in/garbage out and that may be closer to the truth with my
programing even tho the actual
antenna showed a more directional pattern than expected with a dipole
which I assume is the collinear effect. Even tho everything is
consistent with the expected I am not taking money away from anybody
with faulty claims.

But the gall is to expect and demand someone else to

I suppose that can be considered fair comment. "Lazy" was referring to
the
the practice of reprinting from prior editions without review. Many
editions and books 'regurgitate' as it is an inexpensive way to
produce production gains.
>

But Richard, don,t you think that it is a fair observation to say that
if an element produces two maxima current values along the element,
higher values than 'normal' reasonably suggests linear gain ? What is
so wrong by such a statement?
What would this suggest if gain is excluded ? What if I told you that
with using a shoter dipole (4 foot shorter per side) one can lower
the "Q" such
that it provides even shorter turning radius. If it works why kill
yourself
to prove to all why it is so when the customer is convinced that it
works?
Travelling salesmen have an old adage. When you have got the signature
stop talking and get out.

> Fluidmotion with their SteppIR is doing just this and they have no
> problem attracting customers to their booth to purchase simple beams
> of modest specification at more than ambitious prices.

> signed on here to ask for peer review either.

I could have done that also if I was absolutely,absolutely......
sure.
But thoughts of ethics predominate what I thought was right,and was
not right, and buyers lost their money. It depends where you draw the
line, to observe common precautions, or go bankrupt in the long
process that someone such as you would desire. Personaly I was alarmed
at what could go wrong rather than thinking what money I could earn. A
business man has no such hold back viewing investment as a shared risk
which includes customers. It really comes down to what you are willing
to put at risk in the search for money. Some would call it being

chicken!
In the case of the I.R. antenna, as a mechanical engineer I would need
a bulldozer to push me forward.

Enquiries to their
> product here have been occasional but from apparently committed
> buyers. Testimonials from customers have been few, but positive.
>
> However, let me add some perspective to this;
> by their own specs, their antenna offers
> "8.8 Average Gain, Forward dBi (free space)"
> and their claim is
> "Gain that equals or exceeds that of
> antennas on much larger booms!"

I can see how they can make a claim "equal or exceeds" because
manufactures claim the 'peak gain' and ignore the fall off at the band
edges. Where-as the IR antenna can retune, so that the band edge gains
of a fixed antenna can be improved upon.They would also out perform a
trapped tri bander which is often the only antenna that some can put
into their gardens. But as an engineer I would view so many moving
parts on a tower beyond reach does not give me confidence and that is
only the mechanical aspect. But now I notice the comment
"larger booms" which I suspect they are reffering to tribanders.
Depends what they mean by "much".

>
> A simple comparison to the NBS Yagi reveals more gain at 9.68dBi (free
> space). But, hey! Who is going to quibble less than a dB difference?
> (Hardly the loser.) Similarly, who is going to withhold a chuckle
> over their claim?
I don't see how their claim can be faulted other than the lack of
knoweledge about what happens to radiating efficiency when the
radiator is reduced in
length because of the proximity of a dielectric. I asked on a magazine
site what happens in such a case and they said the dielectric can
INCREASE the efficiency.

Even then, there among the smiling is at least one
> fellow opening his wallet. In the arts (I do more than weather) this
> characteristic of the audience is known as "the willing suspension of
> disbelief."

Well I am not convinced either. I have seen so called quality tests
that were continuos in nature as opposed to 'on/off' interuptions. I
have also seen technicians have tests put into motion again,
dismissing the observation that it stopped which means 'stuck'. We
have all done things similar to this in the past
but to climb a tower to do it is more that I would want at my age.

>
> 73's

> Richard Clark, KB7QHC
As a final note, I based my claims on what I call common sense when viewing the current curves and obvious collinear gains based on my personal experience with what is at hand. If a business man can make claims based on that then could possibly an amateur make similar claims that are based on what he feels are honest observations that have not been molded by the advertising department?
If we demand total correctness, total safety, total reliability then we are in a world that cannot contiue. The 'normal' man relies on ethics and personal honesty, if we change to absolutes then this discussion group would not exist,
One posting and then all is done!!!
Can we move on and discuss the mechanics of the design as amateurs in a similar way we would discuss commercial antennas knowing that I am not persuing
commercial interests. Isn't that what hams do?
Regards
Art Unwin KB9MZ......XG.

Given the investment required to put a 3-element yagi on
150 feet of tower, lighting the tower is a trivial expense!

Even without the incredible problem of installing and
keeping such a beast operating and in the air (which
would be a full-time job), there is the problem of keeping
a rotator working for such a behemoth.

Given a choice between a ground-mounted 4-square and a
3-element 160 meter yagi at 150 feet, I'd pick the vertical
array every time, with a proper ground-mounted ground
system. W8JI's experimenting with horizontal antennas
on his 318-, 200- and 160-foot towers, comparing them
to vertical antennas on DX paths confirms the old wisdom
of using vertical(s) for DX applications.

The 3-els at 150' would be great for domestic contesting,
though, with major lobe at 90-degrees! I'd saturate a very-
productive 500-mile circle centered on me in Central Ohio.
That's the reason I have a 40 meter antenna at 35-feet for
Sweepstakes: saturate the east coast!

Use the rest of the 25 acres for phased Beverage receiving
antennas. On 160, he who *hears* best works the most DX!

Source record: 136503

I did a quick run with FEEDPOWR and EZNEC on the following dipole:

Length = 10.192 m
Wire dia = 2.05 mm
Feedline length = 10.9728 m
Braid diameter = 6.35 mm
Loss resistance at base of feedline = 3 ohms

FEEDPOWR reports that:

47.3% of the power is radiated from the "hot" dipole side
29.0% of the power is radiated from the "cold" dipole side
23.7% of the power is radiated from the feedline

EZNEC shows the current on the "hot" side at the center of the antenna to be 0.99 A, at the center of the "cold" side to be 0.15 A, and on the feedline, 0.86 A at the top and 0.82 A at the bottom.

If we assume that the radiated power is proportional to the square of the field strength (not at all a valid assumption, since fields can reinforce or cancel, but it's about the best we can do if we absolutely have to come up with a power), and that the field strength is proportional to the product of the current and the length of conductor the current flows on, we'd conclude from the EZNEC results that:

"Hot" side power = K * (0.99 * 5.096)^2 = K * 25.45
"Cold" side power = K * (0.15 * 5.096)^2 = K * 0.58
Feedline power = K * (0.84 * 10.9728)^2 = K * 120.40

(All wires are just about a multiple of a quarter wavelength long and the currents are sinusoidally distributed, so the current-length integral is very nearly proportional to the simple product when comparing wires.)

which leads to the conclusion that:

17.4% of the power is radiated from the "hot" dipole side
0.4% of the power is radiated from the "cold" dipole side
82.2% of the power is radiated from the feedline.

Quite a difference. Once again, I proudly place myself into your "old wives" category.

Roy Lewallen, W7EL

There have been major changes in zoning and municipal approval laws - thanks to the cellular tower construction boom over the past 8 years.

Some of these changes were citizen demanded (I do not want that "xxx " tower in my backyard), some due to accidents or severe storm damage, others with insurance & liability concerns.

I have noted that mew cellular / PCS antennas in urban areas are now located on existing structures and buildings - with water towers being a favorite -- also sharing among the carriers of sites is becoming more commonplace. Although I see new towers along the interstate and major 2 lane state highways, I see VERY few new towers in the Chicago area (that is what zoning has changed).

3264. Re: Air-Wound Balun Design Info??

Newsgroup: rec.radio.amateur.antenna
Date: 2002-08-18 07:12:42 UTC
From: Roger Leone <arleoneSPAMBLOCK@inreach.com>
Message-ID: <jNH79.1772$i16.203612279@news.inreach.com>
Source record: 136505

Brian:

> Questions: Do air-wound baluns inherently have lower losses than
> ferrite core baluns particularly under high SWR conditions?

Ferrite or powdered iron cores do have some losses but choice of the right core material minimizes them. However, they are never as low loss as air. Also, air core baluns don't saturate as ferrite/powdered iron can, so you can put a lot of RF energy into them. With high SWR, I would suspect the air core balun would have an advantage.

Over what bandwidths?

Bandwidth is the advantage ferrite/powdered iron cores provide. With higher permeability material you need fewer turns of wire to get the necessary inductance for good low frequency performance, and with fewer turns of wire there is less stray capacitance to limit high freq performance. They can give over 10:1 bandwidth. But with an air core balun you should be able to cover at least a 3:1 freq range. For a single band yagi, bandwidth is no problem.

Does anyone have a source for design info for homebrewed
> 1:1 and 4:1 air-wound baluns?

I have been using an air core balun for many years. It was a Bill Orr design from one of the first issues of Ham Radio Magazine from 1968 and was designed for 80 and 40 meters. I haven't used it on 30 meters, but I am guessing it would be OK. There are 3 air core balun designs in his Beam Antenna Handbook covering .54 - 2.5 mHz, 7 - 25 mHz and 14 - 30 mHz. They are all 1:1 ratio using trifilar windings. I suspect you could omit the 3rd winding and go bifilar for 4:1 ratio with the same designs. If you want the details, let me know.

73,

Roger K6XQ

Art, it is all well and good that you put it to the model. If you are not the world's best, that is merely a side issue that no one will dwell on. Allowing us to see the model clears up a lot of issues. Take the small knocks and get over it - confidence comes in no other form.

>But thoughts of ethics predominate what I thought was right
snip

Art, like the typical engineer, you haven't the vaguest notion of how business works. A good business investor doesn't look at the specs, he looks at the niche you fill. If it means selling a dummy load on a

pole, and there is a crowd to buy them knowing full well they are dummy loads on a pole, then there is absolutely no issue of "ethics" involved. There are a bajillion reasons why a business may fail, and I have every hunch you were not a loss center. What you describe is in terms of a guilt trip, take it easy on yourself. The businessmen are professionals, and adults. They know how to take care of themselves. You would have to be an extraordinary charlatan to hoodwink them.

Let's get out of the personal side of things and get back to antennas.

>>
>> A simple comparison to the NBS Yagi reveals more gain at 9.68dBi (free
>> space). But, hey! Who is going to quibble less than a dB difference?
>> (Hardly the loser.) Similarly, who is going to withhold a chuckle
>> over their claim?
>
>I don't see how their claim can be faulted
>

Hi Art,

Their claim did not withstand a simple assault so easily arrived at. I chose the NBS yagi simply because it is in EZNEC's repertoire of example files. I could have browsed around for a better design, or one optimized to the band edges as you noted - and still bested their claim.

The point I would impress upon you is that I forgave their inflated terms because they gave me the numbers, and they look achievable (that is to say, honest). When I compared a random model against those numbers, they proved to be tepid. Again, this was for me a roundabout proof that they were not pencil whipping the specifications for bragging rights.

Once I had resolved those conflicting statements (the claim and the tepid characteristics), I then settled to judge the antenna for its other features. By virtue of their drive system, they could guarantee a match pretty much anywhere. The drive appeared to be robust, and the tubing stout. So in that regard there was quality for money. Now the only thing left that would keep me from buying one is does the technology justify the expense? I come out with a mediocre antenna, but it is simple, robust and covers every band.

And yes, Art, mediocre can be Vastly Superior under certain but common circumstances. You simply have to allow it to be uniformly mediocre. The race is not always won by the swiftest.

> + AEA (www.ryl.nl) but his isoloop seems discontinued.
>

The company Rys here in the Netherlands advertises that he has still an AEA Isoloop on stock.... The correct URL is www.rys.nl
AEA isoloops are not produced anymore. Also these loops are quite sensitive to weather conditions.

> So roughly there is only one available, the two models from MFJ...
>
> Is this design so bad that no other manufacturer wants to sale such
> antennas?
> Surely not.

It's a very good electrical design. Not very solid however when it comes to weather protection.

>
> So where can I find other loops ?
>

AMA antenna's Germany:
www.magneticloop.com

WIMO Germany antenna's and HAM stuff:
www.wimo.de

Ciromazzoni Italy:
http://www.ciromazzoni.com/

Check the new Magnetic Loop forum in German and English language:
http://www.magnetic-loop.de/

And of course you can make your own magnetic loop. There are many URL's where you can find instructions how to make one. Use www.google.com and check for magnetic loop.

I would slow down on the thought of horizontal antennas. I seem to
remember
Tom W ?TI stating that he had a horizontal dipole at some 300 feet and
it did not beat his ground based antenna. He is considered as a very
experienced person in this field so I certainly would look him up. I
seem to remember that he also has a large tract of ground and has also
gone all out to be the best of the best
on top band. Seem to remember that he used a four square phased
verticles with a ton of radials.Either way he certainly knows what he
is talking about.
I assume that your question is relating to a transmitting antenna.
Good luck

>I wouldn't worry about a choke unless you find you need one.<

If it's a split driven element, which I believe it is, it's good engineering practice to install one.

>Mosely doesn't use baluns that I'm aware of.<

When that antenna was built, there was less awareness of the problems associated with common-mode current on the outer shield. Hell, I used to smoke back then...but not anymore.

>If you want to add one just to be
'safe', it shouldn't do any harm.<

It needn't cost anything, either. Just coil up a few feet of cable at the feedpoint (per W7EL's recommendation in the ARRL Handbook).

> 73's
> Richard Clark, KB7QHC

Richard, allow me to have another stab at justifying gain.
The ARRL antenna book states on the Resonant Breaker which is clearly
a relative
of my antenna. It states".......loop is inductively coupled to the
parasitic conductor and is resonated to the desired frequency with a
variable capacitor.
The result is a very high impedance induced in series with the pipe,
wire e.t.c.
This impedance will block the flow of radio frequency currents.
Note it does not say that radiation took place in the coupling area
that could eventually be cancelled, it clearly said 'blocked'.
When modeling my antenna the drop of current is clearly shown.
If one assumes that the statement is correct then it is an easy step
to assume
that the energy that is not consumed in the coupling portion it will
be released
via radiation from the remaining portions of the dipole (resonator)
Thus there is a higher current flow in the remaining electrical
lengths of the dipole and thus provides for collinear gains.
The current curves created by modelling reflect both the antenna
handbooks explanation of what happens because of this coupling and
thus implies verification of my claims. I could also throw in that the
high impedance intregal with this antenna also implies high efficiency
but that can be left to later. With the above statement seemigly
satisfied I think we can say, to reflect Peter O brackets thoughts,

the antenna should also be able to be justified on mathematical terms.

Heathkit made one back in the late 50's. Don't know if AirDux still makes bifilar air-wound inductors, but I built one of the Heathkits back in my novice days--and there was a ton of small-gauge wire in those coils. Can't imagine that would be less lossy than a fractional amount of heavier wire on a #2 core!

Given that power is not a phasor (no phase except direction), how
about Johnson's equation for scalar average power transmitted by a line?

P = (|E+|^2)/Z0 - (|E-|^2)/Z0 (equation 6.17)

Also P = (|I+|^2 * Z0) - (|I-|^2 * Z0)

I was assuming he wanted to route the entire bandwidth of digital TV signals
to the other location. Routing the output of the digital TV box would be
relatively simple as you say. Question is, would it be legal for a ham
to use ham frequencies for such? Then again, at 300 GHz, who would know?

Regarding your technical questions: I suggest that you obtain a copy of the ARRL Antenna Book and the ARRL Handbook. For most of the questions you'll be generating in the beginning, the vintage of the books won't make much difference and the answers are very clearly spelled out in those publications. While you can always get concise answers to specific questions on the newsgroup, the depth of explanation is much greater in the books and the associated drawings and diagrams will help understand the concepts much better.

I use automotive butt connectors to splice my ladder-line. Seems to
work quite well with the help of a few drops of solder.

Using Ohm's law, you would compute power from the voltage or from the current, which is what everybody else in this thread has been arguing should be done. This argument is no argument at all.

> So, power is derived from superposition as are voltage and current. Ohm
> is not violated. Power from one source adds to or subtracts from power
> supplied from other sources. Proof is in the application or removal of
> other sources. The change can be monitored in the heat produced by the
> resistor. Remember some of these sources can be d-c as well as a-c with
> no violation of superposition.

Here's part of a message I posted about a year ago:

However, superposition "is applicable only to linear responses, and the most common nonlinear response - power - is not subject to superposition. For example, consider 2 1-V batteries in series with a 1-ohm resistor. The power delivered to the resistor is obviously 4 watts, but if we mistakenly try to apply superposition we might say that each battery alone furnished 1 watt and thus the total power is 2 watts. This is incorrect."

This direct quote is from Engineering Circuit Analysis by Hayt and Kennedy. The example is for DC, but it applies to AC as well. In any event, the point is *clearly* made that 1 watt cannot be added to 1 watt and still get the correct answer.

You can insist all you want that superposition applies to power, but it simply is not true. Superposition of power is not valid.

Message-ID: <20020818103958.20202.00001188@mb-ms.aol.com>
Source record: 136422

Yesterday I moved my VHF/UHF discone antenna. It was on top of a 15 foot mast, which was attached to a wooden fencepost on my 7' tall wooden fence, a few feet from the side of my house. It performed about as expected, able to get into repeaters 20 - 30 miles away with no problem. Yesterday I moved it on my roof, above my 2m/70cm horizontally polarized yagi (5 elements on each) and my 3 element 6m yagi. All of a sudden the receive has gone way down. A repeater about 20 miles away that used to come in at an S7 doesn't even show anything on the meter. The local repeater comes in fine, but it seems that the signal has dropped very slightly. Could the yagi's be interacting with the discone, possibly causing the signal to be reflected up and thus reducing the range of the antenna? I plan on moving the antenna back to where it was, but we're having some super hot days here in NJ so I can't get up onto the roof right now.

Hi Walt,
I'm not going to comment on what Steve said. Like I mentioned in my
previous post, equations 4.23, 4.24, and 4.25 are just general
expressions for voltage and current at an arbitrary point on the line.
These may be used later on by Johnson in his standing wave analysis,
but there is no mention of SWR or standing waves in that whole section
spanning pages 98 to 101. In fact, standing waves aren't even
introduced until page 107. Based on what Johnson has, a term in
e^(-gamma*X) or e^(gamma*d) would be a forward wave component. 73,
Bill N3WK

Very possibly, indeed. How high is the discone above the first yagi below?

O.K. Richard you have had time to digest and I expect that you now
agree that:

1. The antenna is rotatable and it is frequequency changabable
using remote
control.
2.From the previous post I think we can say that we have
established that we have blocked current flow in the center of the
dipole.
Now following in the line of thinking that you are most
comfortablelet me move sideways a bit. It has been said that maximum
radiation is obtained where energy
is forced to radiate from a single point which means

di/dt = an unbelievable high number

for others that are following this is tantamount to having a sprinter
run the 100 metres in an infitesimaly short time where all his energy
is released in a short unmeasurable pulse that was formally expended
over a longer length of time
since the length of the run is physically longer than just one step.
So getting back to his original statement it means we are
pursueing a shorter time to release energy available with out having
to use a half wave
radiator. (remember, the rate of change of current flow is what
determines in the final analysis the radiation from a radiator)

Coming back to my antennaa and it to be used for 10 metres.
With a 20 metre length radiatir one can easily deduce that that there
is a normal 10 metre current curve at each side.
Now looking at one half of the antenna which is 1/2 wave element
for 10 metres we can see that we have shortened the electrical length
required because we have effectively shortened the radiator be cause
of the blocked current flow
at on end where coupling occurs.

So getting back to the simple di/dt formula by reducing the
time for
maximum energy exchanged (to radiation energy

the resultant to di/dt has increased. But we cannot create enrgy so it follows that peak current will increase which inturn gives a power gain.
Now ignoring the fact that two current maxima provides for linear gain we can see from the antenna current curve on each side that the areas under the current curves which represents energy available has changed in physical shape which correllates to an increase in radiation of each 10 metre dipole over one that stands alone.

So getting back to 'gain' over a traditional multiband antenna,
where the physical length is represented by 20 metres, half wave
we have :
1. A power gain from each individual 10 metre radiator over two separate half w3ave dipoles

2. We also further increase 'gains' because of the collinear effect,
Which ,when combined with the power gain provided by each individual
radiator it becomes obvious that gains have escalated in a large way.

So we are not looking at just 1 db gain which you have implied is a
significant improvement but much larger gains.

Reflecting back to radiation from a point. The change in effective or electrical length reflects a start in the pursuit of the final pot of gold.
I can also use a dipole radiator that is shorter in length than the standard dipole which effectively shortens 'dt' even further.
Piling on, this antenna can be made narrow banded or broad banded for a particular frequency thus focussing energy only over a band width that CW or audio would require.

So Richard I have made the above attempt to explain what happens and why . and also why I can assume that gains obtained are major compared to prior
state of the art antennas.
These are my explanations for my antenna, so naturally I should be
expected that with my lack of knoweledge with respect to I may have twisted laws enunciated by Maxwell ,Kirchoff. the Lenz guy and others
to unintended manipulation to produce what I would like to see.
Hopefully with this debate opened in a generous way by yourself, others
will be inclined to join and add comments and possibly provide the principles of this antenna to rejuvinate the standard

wire antennas shown in Antenna books and encourage hams to
re-enter the experimental side of antennas .

Have a great week end everybody.
Regards
Art Unwin KB9MZ......XG

Johnson's equations calculate the average power. As written, they're correct only if Z0 is purely real.

Power is a time-varying quantity. It does have frequency and time phase. (If this isn't clear, please re-read my posting.) It could be expressed as a combination of a DC term and a phasor, but I can't see of what use that would be. For one thing, it couldn't be used with voltage or current phasors in the same circuit because of the different frequencies. Average power, of course, is not time-varying in a steady state circuit.

could be if its less than 5 or 6 feet above the other antennas
also if you changed your coax it could be that as well the longer the run of coax the more loss you have in it so if you have some of that wonderfully lossy radio shack coax at 2 meters at 100 foot run you are losing over half your signal coming in and half your power going out and it gets worse the higher in freq you go
good luck

Wow. I never knew that every single evemt involving a US military or NASA vehicle was the result of those pesky Russians. Not only that, but every "natural" phenomenon such as earthquake, flood etc too. Me, I'd love to know how a country that cannot even afford to pay it's military personnel can afford the electricity.

You missed out some other "proven" attacks of Russian EM weapons - what about the storms, hurricanes and bad winter snows - obviously EM weapons in "climate-change" mode.

I am also quite prepeared to believe that the election of "Dubbya" was the result of some kind of foreign interference, maybe EM directed brainwashing or mind-control.

By the way, if it's all these pesky Ruskies doing this EM stuff, then what is that great big array in Alaska irradiating the atmosphere for? Peaceful climnate study, I think not!

I'm sure "Fractenna" will be able to come up with a good design here. How about 6 inches of wire bent into a pretty snowflake shape. Four of these "ultimate" antennas would give you directionality with proper switching and phasing. Best thing is though the enormous bandwidth would allow you to operate all over both bands without a tuner.

Then you can turn the other 24.99 acres into a nice flower garden.

Nope. What you describe may occur, but not in every band. This is
the failure of your enthusiasm: find the best and apply it with a
broad brush painting everything sky blue. When obvious flaws are
exposed beneath this veneer of color, the whole work becomes suspect.

snip

You are describing the isolation of elements common to the discussion
of traps. OK, you don't have traps, but then neither does the
standard dipole you replaced that has identical characteristics. So,
in fact you have "done" nothing because it is the natural tendency of
the radiator to act this way in the first place. Don't take credit
for mother nature, Art.

snip
>
> So we are not looking at just 1 db gain which you have implied is

No Art, you have not shown this at all. Adept modelers have in fact proven that what you describe "is no different" from the structure it replaces. I must presume that through your refusal to share your modeling that this characteristic you ascribe to your design is flawed. As you have already admitted to being a poor modeler and still show no inclination to seek improvement - No, your design does not exhibit the gain you claim.

It's very easy to homebrew your own small loop.
That may be why so few manufacturers produce
them. MFJ caters to the gullible few IMHO.

I have an old MFJ, but only because the remote
controller had been damaged -- I got it for
$100 Canadian, and repaired the controller in
short order (dirty switches). If you want to
build your own for a specific frequency it is
quite simple as you use a piece of coax for the
capacitor and just cut it to length. If you are
lucky, you may just find a good hi voltage variable
somewhere at a good price.

> manual..
<snip>

Hi Scott

The balun is not required for matching purposes, it is purely there in some installation for EMC purposes, stopping RF currents in the outside of the feeder which may potentially radiate. This risk rises if you are one of those people who likes to use a tuner to extend the workable frequency range of your beam beyond its design. I personally would always recommend some kind of choke balun, usually just a coil of coax, when feeding a balanced antenna with unbalanced line. Living in a built up area I feel the need to take a "belt and braces" approach to EMC. The same may not be true of your locale.

It costs next to nothing for the extra coax, takes no time and can do no harm. Much easier to put it in at the start than climb the tower and retro fit it.

But, the antenna will function fine without it, and you may well be lucky EMC wise.

>It's probably not even 6 inches above the yagi.<

That explains it! The larger antenna underneath looks like ground to the discone. Move it up 5 feet and prepare to see a huge difference. I use one here, and it works great.

anything on
> the meter. <snip>

S7 to nothing is IMHO too big a drop to be down to purely antenna
interaction. The discone wants to be a metre or more away from the beam, but
first I think a check of the feeder and connectors is the order of the day.

Good luck

Hi Art,

You are being too myopic by examining ONLY your antenna. This is the failure of your style in that you show no correlation to other models (and still refuse to release your own). In other words, what you describe above is commonplace for any similar sized structure. As you describe yourself as a poor modeler, I should point out this has been already confirmed by competent modelers.

"I have access to 25 acres and want to erect the "ultimate" 160/80
directional atenna.

It is prudent to see what the most successful DXers have done and do likewise. John Devoldere, ON4UN has a nice book, "Low-Band DXing" published by ARRL and likely available through RSGB or elsewhere.

In ON4UN`s book is a survey of equipment and antennas used by some of the best known DXers.

The Beverage antenna is the runaway favorite receiving antenna.

Many other antennas are used with great success for transmitting. The Beverage is excluded by its loss. This is no problem for reception because this loss attenuates interference as much as the signal and this can be offset with receiver gain.

The inverted V antenna is one of the most popular with this group of outstanding DXers. There is no clear majority. The inverted V does not require as much height, space, or support as some of the other antennas on 80-M and 160-M. This may account for its popularity.

Borrow a copy of ON4UN`s book and pick and choose for yourself.

Best regards, Richard Harrison, KB5WZI

Bill, N3WK wrote:
"For example consider (2) 1-V batteries in series with a 1-ohm
resistor."

Short out one battery and the remaining 1-V battery puts one amp through the resistor. With two batteries you have 2-V and 2-A. It`s a no-brainer. 4-watts. You add the volts and you add the currents. Then, you multiply.

So power is derived from superposition as are voltage and current. Ohm is not violated. It`s not what you do but the way that you do it.

Best regards, Richard Harrison, KB5WZI

What is Steve's justification for assuming that you can add two scalar powers and get more power in the sum than exists in the individual terms? Every power engineer in the world would laugh at Steve's equation, 75w + 8.33w = 133.33w

Johnson assumes that we can subtract the power in the individual reflected wave from the power in the individual forward wave to get the power delivered to the load. How is that different from assuming power in individual waves? Not arguing, just asking.

> travelling wave with voltage and current V1, I1 at a given point and
> reverse travelling wave V2, I2 at the same point is V1 + V2, I1 - I2.

Yep, reverse traveling waves are supposed to have the voltage and current 180 degrees out of phase. And honoring the accepted rules for what happens to voltages and currents at a reflection point is tricky depending on whether the load is higher or lower impedance than Z0.

> Do your calculations with the voltage and current waves. When you're
> done, you can calculate the power from the source and into the load, and
> you'll get the right answer. If you declare that the power in the
> forward wave plus the power in the reverse wave have to add up to the
> power in the superimposed V and I waves, you'll get the wrong answer
> more often than not.

Here's an interesting example, I think suggested by Bart, wb6hqk. I'll take it in two steps so the final configuration will be clear. All components are lossless.

100w XMTR---tuner---50 ohm feedline---+---150 ohm load

I think we can all agree that the SWR on the 50 ohm feedline is 3:1,
that 100w makes it to the load, and there are no steady-state reflections
between the tuner and XMTR. So the forward power must be 133.33 watts and
the reflected power 33.33 watts.

Now replace the 150 ohm load with 1/4WL of 150 ohm line terminated in a
50 ohm load.

100w XMTR---tuner---50 ohm feedline---+---1/4WL 150 ohm feedline---50 ohm load

The quarter-wave transformer transforms the 50 ohm load impedance to 150 ohms
seen at the 50/150 ohm transition point so steady-state power conditions on the
50 ohm feedline have not changed. There is still a 3:1 SWR on the 50 ohm feedline,
133.33w of forward power, 33.33w of reflected power, and 100w delivered to the
150 ohm feedline.

On the 150 ohm feedline, we also have an SWR of 3:1, 133.33w of forward power,
and 33.33w of reflected power because the reflection coefficient at the load
is also 0.5. The load is accepting (dissipating) 100w. There is obviously a mis-
match at the 50 ohm to 150 ohm transition point between the feedlines so reflected
energy from the load should be crossing the 150/50 ohm junction point. But is it?

I have tried Steve's method of analysis on this example and failed to get it to
work. Can anyone help with that analysis?

Hi All

I have been thinking about getting on 160 and plan to build myself a Inverted 'L' or grounded Long Wire for Tx/Rx

Question is, I don't like the idea of bringing the 'bare' wire into the shack with all that RF. So is there any way to bring it into the shack by say Coax ?. Also if I bring the Long Wire through a wooden window will that cause any problems ?.

Also any views on Topband antennas for a small garden, greatly appreciated.

Ideally, you tie the coax shield to a large ground plane. The least you
should to do is tie the coax shield to a counterpoise.

Source record: 136449

Tom, N0SS has published an article on these newsgroups several times.
Summarizing his measurements concludes that 1:1 coaxial balun with an
excellent choking reactance for 10 through 20 meters can be made by winding
6 turns of RG-213 on a 4 inch pVC sewer pipe. For 40 or 30 meters use 12
turns. Wind the turns as a single layer

Oh, and by the way, you say about 70 feet. Does this mean you have short pieces with the bent parts cut out? If so, forget it. I have seen several people try to reproduce the bolt holes at the joints, and in 45G no less, and all were unsuccessful. You can't drill them accurately enough without a fixture, and when you enlarge the holes to make the bolts fit, you end up with loose, wobbly joints. Go buy new tower. The $1,000 will be cheap compared to lawyer fees and court costs when the thing falls on someone.

No, you'll see 450, not 150 ohms at the input end of the 150 ohm line.
You'd see 150 ohms only if the termination resistor were 150 ohms. The
conditions on the 50 ohm feedline have changed.

I see the difference in construction from the Cushcraft website R7/R8 uses
trombone type capacitors to resonate the traps, the R7000/ R8000 appears not
to, so does it use internal caps inside the inductors? anyone any experience
of either type and preferences, mechanical electrical etc?
I have used an R5, but now folded in high winds looking for a replacement.

Gullible doesn't begin to cover it! Check out the two German manufacturers mentioned earlier in this thread. They have many more models to offer than MFJ, but even the cheapest, smallest runs almost $200US *more* than the MFJ (and the $$$-est over $2K!!!). I can't see why they can get away with these prices, any of them. HV vacuum and air variable caps cost a bundle, I'll say.

But has everyone forgotten that old ham virtue, the homebrewed? I have made several small loops for bands 80-10 (not in one antenna!), sizes from 1M to almost 4M diameter, and made my own caps. My most recent is for 40-30 meters, about 2M diameter, using continuous .625" copper refrigerator tubing, resonated with a series dual-piston ("trombone") capacitor, with sheet PTFE dielectric (>20 kV rating) and sections of copper water pipe as rotors/stators.

Cost: about $30, including feedline (less remote motor drive, I'll add it later, and it will add another $15-20 to the cost). So, I have a complete working loop antenna system for about $50, and I am confident that it is closely favorably comparable to any commercially manufactured, with the exception of radiation resistance. On that measure, I am certain my loop beats all the commercials, being made of copper rather than aluminum! Anyone can do this with a minimum of tools, test gear, exotic parts & materials, and homebrew aptitude. And these antennas do work, as they say, remarkably well.

I have a TA33 and use a coil of coax for a balun as they recommend in the instructions that
came with it.
They also recommend a shorting strap from the boom to the element that connects to the shield
of the coax. With the shorting strap I found that the antenna had two resonant points. On 20
meters it had one at about 14.300 and a second one at around 13.8 mhz if I remember right.
With the shorting strap it would exhibit a nice broad band swr of course. With the shorting strap
removed it only had one resonant point which was sharper than with the strap. The resonant
bandwidth without the strap acted more like a 3 element beam should. It had similar response
on all 3 bands each way.

I discussed this with Mosley and got no answer. They asked for swr curves from me etc, like
they had never heard of this before. Never did get a satisfactory answer from them. I ended up
leaving the shorting strap off.
It acted like it detuned one side of the element with it on.

I think that they used it to try and make the swr curve wider on the antenna.

As I recall, the R7 preceded the R7000 and used an older style trombone trap.
The R8 is the current production model--I'm not aware that there is a R8000.

Twisting and soldering copperweld stranded wire is ugly. The individual
wires are not well behaved.

Darn, I must have copied the example down wrong. Maybe it was 86.6 ohm
feedline or an 86.6 ohm load.

Current AES catalog shows an R8 for 6 thru 40 meters, and an R6000 for 6 thru 20 meters, plus a little MA5V vertical for 20 thru 10.

When I said about 70', it was because I don't know how much of it I can
actually use. As it turns out, it looks more like 50'. I'll probably
invest in another section or so. One of the sections I planned to use has a
broken leg, so it's pretty much scrap, unless someone has a suggestion on an
alternate use.

Copperweld being copper on steel? I have the ladder line on hand but
haven't played with it yet. Thanks for the heads up.

I will be using automotive-type bullet connectors for the joints I
need to take apart. I guess I'll solder the crimped spots for
reliability.

3331. Crimp-style RF connectors - Diagrams On How to Prepare Coax

Newsgroup: rec.radio.amateur.antenna
Date: 2002-08-19 03:00:40 UTC
From: Tony Hackenberg <tony.hackenberg@worldnet.att.net>
Message-ID: <sbZ79.19019$Ke2.1552327@bgtnsc04-news.ops.worldnet.att.net>
Source record: 136371

Could you refer me to a web site (or other resource) that would show me how to install the following 'crimp-style' RF connectors onto the coax types listed below?

ITEM# DESCRIPTION
------------ -------------------------------------
(1) RFC505 PL-259 Crimp for RG-58;
(2) RFC508-X PL-259 Crimp for RG-8X; and
(3) RFC601-1X Mini UHF(F) Crimp for RG-8X.

I searched the Web but could not locate any diagrams or information. I also tried the ARRL site and the ARRL 2002 Handbook. Unfortunately, I came up with nothing.

I purchased these crimp-style RF connectors from The R.F. Connection (http://www.therfc.com). The ITEM#s listed above are their part numbers. I contacted them but did not point me to any diagrams or schematics on how to properly cut/prepare the coax for assembly onto those crimpable connectors.

73,
Tony/WA8SSQ

3332. Solder-style RF connectors - Diagrams On How to Prepare Coax

Message-ID: <emZ79.19046$Ke2.1552745@bgtnsc04-news.ops.worldnet.att.net>
Source record: 136373

Could you refer me to a web site (or other resource) showing how to install the following 'solder-style' RF connectors onto the coax types listed below?

ITEM# DESCRIPTION
--- ---
(1) PL259 PL-259 Solder type (with adapter below) and
(2) UG-176/U Reducer to allow PL-259 to fit RG-8X coax cable.

I searched the Web but could not locate any diagrams or information. I also tried the ARRL site and the ARRL 2002 Handbook. Unfortunately, I came up with nothing.

My reference library once held diagrams on how to do all kinds of RF connectors. I think a very old issue of CQ or 73 Magazine contained these diagrams. However, I could not locate it in my library. I guess I lost the issue.

73,
Tony/WA8SSQ

From: ckesler@chartermi.net
Message-ID: <um0ph7q7uuqs81@corp.supernews.com>
Source record: 136374

I have a Yaesu FT-100D which has some built in features for the ATAS-100. Has anyone used an ATAS-100 or heard anything good or bad about it? I'm looking for a portable, multiple band, HF antenna that actually performs well. I bought a MFJ-1622 apartment antenna. I am not impressed with its performance. MFJ says that it works well on all bands from 2 meter to 40 meter. That's not true. I can work 20 meter with it sometimes, and have never been able to get out on 40 meter. If anyone has any experience using an ATAS-100 please let me know what you think of it. If anyone has any suggestions for a nice portable HF antenna let me know also. The July QST had some plans for a nice portable HF... has anyone tried that? If so, let me know if it was worth it.

Thanks,

Kes,
KC8UIE

While I might infer from your choices your speaking about mobile operations,
it would help if your question were a bit more specific. Do you want to work
local, DX, or what is the requirements you wish to solve. My answer would e
a screwdriver antenna for 40-10.

3341. Parallel Dipoles for 20 and 17?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-08-19 08:53:02 UTC
From: n2cqr@clix.pt
Message-ID: <3d60b0af.38696775@news.clix.pt>
Source record: 136382

My efforts to use coaxial traps to convert my 17 meter rotatable dipole for 20 and 17 meter use didn't work out. So now I'm looking at other options.

What do you guys think would happen if I tried to add a 20 meter dipole in parallel with he 17 meter wire element (using the same piece of coax)? The antennas would be very close together, separated only by the diameter of the fishing pole supports.

Could someone run this antenna with modeling software to see if it would work. I'm concerned about the frequencies being so close...

Use the floridic acid (watered down of course!) that is used to clean
AC coils outside...(which are aluminum!)....works really well and makes
the antenna look brand new....
WARNING this is an acid...be SURE to cut it down with water before
using.....follow the instructions TO THE LETTER!!!
Beats the hell out of scrubbing with a pad....
AL Oxide is only of concern though where the elements come together....
On the rest of the elements, it actually protects..

Kes,
The early ATAS-100's had some problems, for some
reason they would 'lock-up' the system and require
everything to be turned off/on to get it working again.
I understand that Yaesu has cured that problem.
Any mobile antenna is a 'compromise' and will very
seldom work as well as an antenna normally used at a
'fixed' location, as a 'real live' full sized antenna
will. If your situation is that you can't have a full
sized antenna, then the ATAS-100 will probably work as
well as any other 'compromise' antenna of comparable
size.
'Doc

Source record: 136390

ANY line 1/2wave in length (x velocity factor of course) will repeat
the Z at one end to the other....SOOO on a fixed freq antenna, use
ANY line that is 1/2wl x VF in length ...or ANY multiple of said length
(As long as it is a Mutl of the 1/2 x VF)
That way the dipole impeadance is correctly reflected to the xmtr...

OF course if the antenna is resonant and the feedline is the same Z
as the feedpoint is, then ANY length will do ok....(say the dipole
is a true 72ohms...then ANY length of RG59, etc will work....but
any length of RG58 other than Nx1/2wlxVF lengths will not be correct!)

Source record: 136391

The band has been closed lately.....the antenna should have about
a 2MHz MAX SWR of 2:1 so if it is 1:1 at 52.525, it will only cover
from 52-54 MHz ok...or maybe a little lower....if you want to use it
on SSB and FM, you need to move the resonant freq down to 51.2 MHz..
but this will cause the SWR at 52.525 to be higher than 2:1 likely.

Time for a high horizontal omni antenna on 6 for SSB! like a turnstile
or similar!

Chris

Source record: 136392

The fact it handles all three at once is no secret.....it is merely
physics!!!

ANY antenna that is multiresonant will work with the same number of
xmtrs into it at the same time....the problem is making it work with-
out blowing up the xmtrs!!! This is done by the diplexers!!!
They are merely LP, HP and combination filters that allow the
RF from the proper band to flow in and onto the antenna side..
without feeding back into the other ports....a LP filter will NOT
pass higher freqs (depending on the design cutoff freq and isolation)
and a HP will not pass LOWER freqs below a certain point...
a combo or BandPass filter only allows those signals within a certain
range to pass....SOOO each port is protected from the others (up
to a certain power level!).....and they merely mix together out the
common port to the antenna...NOW if the antenna goes bad on ONE band,
you will have a serious problem as the system is no longer balanced
and SWRs on the band in question will cause serious overheating,
etc in the components on the other bands.....possibly causing them
to burn out and then that will damage the xmtr, etc on that port!
Its all a balanced system (they like to see 50ohms at all ports!)..
remove one side and it becomes a nasty unbalanced thing! :)
Hope that helps

The long delays for postings to be placed for view
is causing cross talk.

What you say above is MAJOR to the antenna and may well be the hurdle
that is preventing the acceptance of my antenna.

Your statement implies that the ARRL publication is in error
as it does not relate to facts on all frequencies.

You infer from this that these 'gaps' in frequency coverage
or more specifically "bands', the statement in the book does NOT
apply.

Since the specific antenna range is for 20 thru 10 metres

Would you agree that it DOES happen on 10 metres for example,
for starters, so the debate can continue.

This is very important because it affects the viability
of frequency change and rotatabilility which you
previously accepted ! Is this now being thrown out of the window ?

In addition, could you shed some light as to what in the ARRL
statement is in error and how it should be corrected ?

I see no point at this time to continue with the rest of your
posting at this time because of the seriousness of your statement
and the extrordinary slow pace that this net is being run.

It should be in your ARRL Handbook. I've got the year 2000 book, and in chapter
22, "Station Setup," page 22.7 shows a diagram of how to cut your coax and
install it into these two connectors.

Bill, seems to me you are trying to solve your problem the hard way.
I have a 33ft rotatable dipole that works on all ham frequencies
above 14MHz. I vary the length of the ladder-line to achieve a
match on all those bands without an antenna tuner.

In particular, for operation on 20m and 17m, the "magic" lengths of
450 ohm ladder-line *calculate* out to be:

450 ohm ladder-line Lengths
20m 17m

62.3ft 66.2ft 1st close point

93.5ft 90.6ft 2nd close point

These are calculated values and you would need to add or subtract a
few feet to match your QTH but you can tune the rotatable dipole to
20m by adding or subtracting to the ladder-line length until you get
a multiple of 1/2WL on 20m. Then add or subtract whatever length is
necessary to resonate your antenna system on 17m. Whenever you want
to change bands, simply switch the single length of ladder-line in
or out. You can do it with relays, knife switches, or manually with
banana plugs. You only to deal with a single three or four foot piece
of ladder-line. For my rotatable dipole, the difference in ladder-line
length on 20m and 17m is an actual three feet in reality.

Or if you don't mind using an antenna tuner, find the "magic" lengths
at your QTH, choose a length halfway in between, and use a tuner.

I must have copied the example down wrong but the following should do.

100w XMTR---tuner---50 ohm feedline---+---1/4WL 86.6 ohm feedline---50 ohm load

Can someone show me how to analyze what happens at the 50/86.6 ohm junction
using Steve's method of deriving voltages from calculated powers?

One more thought: What do you do at the stainless antenna posts with
the unruly Copperweld wires? If you crimp on an apropriate connector,
it will be subject to corrosion. What about using a butt connector to
go to insulated copper 14 gauge for maybe 6"? Then you could solder
the butt and coat it with epoxy sealer or hrink tubing. Only the
copper wire would be in the breeze and you bend that around the posts
and tighten the nuts.

If this makes sense, should the copper wire be solid or stranded (and
tinned at the end)?

Does connecting Copperweld to copper in an HF feedline cause anything
strange to happen?

Hi,

Have been using a 20 year old Antenna Specialists Model MONR 31 aerial in my attic for frequencies over
30 MHz. They still apparently sell this model.

Works O.K., but was wondering if the Radio Shack Catalog No.-Model 20-043 "Outdoor Scanner/Ham DISCONE Antenna" "might" be better?

Both antennas look fairly similar, with the radial arms, etc.

Anyone have any experience with either of these? Opinions would be appreciated.

Thanks,
Bob

Hi Fred

My email address is not very neat. Then again, I don't attack Mr Bush - I just dare to question the direction in which he is leading us. Unfortunately it is "us", since Mr Blair just does as he's told, as do most of the other NATO leaders. Wonder why. Is that a small globe of white light I see above 10 Downing St.....

Alec

PS For those Americans with a similar knowledge of other countries to their president, I'd better explain that 10 Downing Street is the residence of the British Prime Minister, who is called Tony Blair - short for "Anthony" by the way.

Indeed they probably do exist. I think what people have a problem with is the idea that every "natural" disaster and every event involving loss of US military personnel is down to Russia, which is now basically a third world country. If these weapons do exist and are in use, it is most likely that they would be in the hands of the worlds richest country, not one of the poorest.

That said, I don't believe that the US have yet perfected such a weapon, if they had we would all know about it. America's "national security requirements" would have required its use on all of us by now for daring to question "Dubbya".

Any dissimilar metals will be subject to corrosion, some worse than others.
In my particular configuration, there is the need to connect copper to
aluminum which causes known problems. Lead-tin solder is more similar to
aluminum in the galvanic table than is copper so I use solder covered lugs
at the aluminum contact point. I also use antioxidants at that point and try
to waterproof the connection. It's not perfect but it is probably good enough.
Stainless steel is very close to lead-tin solders in the galvanic table, so
solder the copper wire into a solder-tinned lug and you should be (almost)
home free. Polyphaser has an application note on the subject that you can
download. The ID of the ap note is PTD1010.

Unfortunately I can't move the antenna any higher. I'm going to have to put it back where it was at before I put it on the roof, back around 15 feet above the ground.

Lithium grease under various trade names (Lith-Ease is one) is good for
virtually all outside antenna hardware. I have used it for thrust bearings
and tower hardware. It protects the outside
from rust and weather. I then use Pre-Lube 6 or similar for say wire rope
or cables where you want the lubricant to sink in. (DO NOT USE WD-40).

Cushcraft closed out much of its HF antennas as the amateur HF market is very small and there are many competitors. You gotta make money and thats hard in this market. They still make the 7 El tri-bander, the Log Yagi, the A3WS, and the XM240 (2 eol 40). Too bad as the 4 el beams were quite good.

Dave K4JRB

3373. Re: 'Nother question about ladderline

Newsgroup: rec.radio.amateur.antenna

From: 'Doc <w5lz@icok.net>
Message-ID: <3D613547.49001C42@icok.net>
Source record: 136414

Ken,
I don't seem to have the problems using copperweld
wire that others seem to have. The only 'posts' I have
to make a connection to with the ladder line are on a
tuner, and I just form the copperweld into a loop and
it's clamped between two washers on the posts. I have to
re-tighten the wing-nuts occasionally, but that's about
it.
I've used both the single conductor and the stranded
conductor ladder line and can't tell much difference
between them. I don't think there is much difference.
As far as soldering copperweld wire, make a good mechanical
joint, then solder it, no big deal. If your really that
worried about soldering copperweld, make a 'linesman' splice,
then solder it. If that doesn't make good enough connection,
'ain't nuthin' gonna work anyway...
'Doc

What you are describing is a choke. I know it's called a "choke balun" even by manufacturers. But it remains a choke, not a balun in the sense that its function is not to transfer power to a balanced system, but rather to inhibit power (ie choke it) to one side of the system. Sure it "works" in terms of inhibiting rf current on the coax outer shield (when that is the problem), but how could it not, at the same time, inhibit the rf current in the antenna leg it is attached to?

My apologies for fanning a religious war, but the original poster needs to know that not all things called baluns are, even if they are air wound... Sigh...

Source record: 136322

Hi,

Have a new receiver, and have gotten in the habit of diconnecting my HF and VHF aerials whenever there is a
summer storm in the area. We tend to have many around here.

Not too worried about direct lightning hits, but am very concerned about induced voltages from "nearby" strikes,
and also static buildup. Antennas are receive only, and located in the attic (a discone, and a random-length wire for the HF).

The connecting and disconnecting has gotten to be a real pain, so, it looks like I am in the market for two antenna switches.

The units that have the the unused terminal grounded sounds like the way to go, certainly.

Smaller the Switch size, the better.

Would appreciate any opinions on, and experiences with, the four brands in the Universal Radio catalog, or on any others.

Alpha Delta
Daiwa
MFJ
Diamond (unused grounded?)

Much thanks,
Bob

When a common-mode choke is placed at a BAlanced to UNbalanced junction,
doesn't it become a balun by default?

>attic (a discone, and a random-length wire for the HF).

Hi Bob, A really simple way is: go to your local Radio Shack, get one of their Aluminum project boxes, about the size you want. Get as many single pole-double throw toggle or slide switches as you have antennas you want to ground, get appropriate connectors for the feedlines, and build your own. Take about an hour tops. Might cost $10 for the materials.
Since the antennas are in the attic, static buildup should be your only concern, and the above arrangement would handle it as well as the more expensive "store bought" switches. And you built it yourself.

Just eyeball it. Get it close (move the pot arm a little if you have
to) and once you get power to it, it'll line right up.

Remember this; there are two kinds of hams: those who have had ball
bearings all over the floor, and those who have never taken apart a
HAM Series rotator.

You wouldn't make a profit out of that though would you. Anyway, don't get the idea that there was any kind of moral portion to the US decision to enter the war. America has and only ever will act when it's own national (read financial) interests are at stake.

Not if you tin the wire before you cut it. Coat a two inch section of wire with solder, and cut it in the middle. A propane torch and large diameter solder (rosin core, of course) makes short work of it.

Bob,
As long as the antennas are for receive ony, it
really doesn't take much of a switch at all. A simple
SPDT switch with appropriate connectors would work as
well as any of those you listed. If you don't want to
build a switch, I'd opt for the cheapest coaxial switch
I could find.

Hello Randy,

I have no experience of the 5 USA antennas you mention. I do not even know what any of them look like. But please take the following seriously. You will be on the air much sooner if you don't buy any of them! If you do buy one, especially if you have no experience to compare it with, on balconies you will eventually be very disappointed. On the otherhand you will be very much the wiser.

Consider a figure of merit to be 6dB or or one S-unit. Ignore any performance differences of less than 0.5 dB.

Assuming you do not have a balcony as big as my small back yard and that you may occasionally wish to go portable, I judge the most important part of the radiating system will be the ground connection - if that is a worthy name for it. None of the multi-band antennas you mention will work as intended without a good ground electrode system. And none of them will work better than a simple length of wire associated with whatever ground system you can provide from your balcony.

Whatever antenna you may end up with an antenna tuner will be assential.

Invest in a tuner rather than a commercial antenna. An expensive all-singing, all-dancing tuner is not necessary because you can make one yourself. One tapped coil wound on an an empty, cardboard, toilet roll tube and one variable 200 or 300pF capacitor will do fine. Alligator or crocodile clips are the best inventions since sliced bread. On second thoughts the alligator clips may claim precedence.

The antenna can be an almost invisible, thin, plasic-insulated length of stranded (flexible) wire extended from the balcony. If you can extend it outwards to another building or tree all to the good. If not, then take it loosly up the outside of the building. Or if the balcony is high above ground level then allow the wire to dangle downwards towards the general direction of the ground. But outwards and upwards is always the best. I've tried it successfully in all configurations. On the higher frequencies, such as the 10m band, a wire loosely attached to a fishing rod works fine.

For the ground system, only the domestic hot+cold water plumbing plus central-heating plus all the 60Hz power wiring is available. But this makes quite a reasonable ground. On the lower frequencies there may be noise (crackles and pops). But there's nothing you can do about that on a balcony. That's life!

Be prepared to change the antenna wire length between bands. But that is a very simple matter. It takes the load off the tuner. Wire length with a tuner is very non-critical - any length longer than 0.2 wavelenghs will do

fine.

When portable, just throw the antenna wire over a tree. If near a stream or a pool of dirty or salty water the ground can consist of a submerged 12" square plate plus the vehicle plus anything else which might be available. A single ground rod is virtually useless unless in waterlogged polluted/contaminated ground.

The performance of small vertical antennas as described by manufacturers and salesmen is usually nonsense. There is nothing more efficient than a simple length of wire above a good ground. But it must be said that at about 21MHz and higher frequencies the roof of a vehicle makes a good, high efficient ground. (But you are also interested in lower freqs. So use a longer antenna wire).

If you MUST buy a commercial antenna for use in a restricted space, such as a balcony, then my recommendation is a Magloop tuned for three bands with a vaccuum variable capacitor. It does not need any ground. It is expensive but may not need a seperate tuner. From a radiating efficiency point of view there is nothing to choose between manufacturers. Choose the largest loop diameter available and consider only mechanical construction and reliability. Or make one yourself if you have the necessary facilities!

A restricted space does not handicap experimentation and ingenuity. Indeed it incites the best from radio amateurs. There's ample scope. Restrict power to 100 watts. Do not be misled by the adverts and old wives. Enjoy your DX!

I've used a RS discone on a 20' rooftop mast for over 11 years, with terrific results.

I modified the antenna by adding the (then not included) top element to improve reception from 25-50 MHz. I had to do some "social engineering" with the parts department at Diamond Antennas (the manufacturer of the RS discone) to buy the top element, as they normally wouldn't sell it to anyone who hadn't purchased the Diamond version, but it was worth it. I believe that the RS version now includes the top element.

For the money, it's a fine receive antenna. Experiments with 2 meter transmit/receive went well too, despite a measured 1.7:1 SWR at 2 m. freqs.

It certainly has been durable; in over 11 years, I haven't lost one element, the antenna has been pretty corrosion resistant, and even a bird's nest at the top hasn't hurt performance too much.

I'd buy another one if I had to. It's a good antenna.

> about it?

It works very well on the car; easily the best mobile antenna I've ever had. (Not that I've had lots of antennas on the car.) However, remember that if you use it at home, you'll have to provide some sort of ground system for it. If you mount it on the roof, a couple long counterpoise wires should help a lot.

> I'm looking for a portable, multiple band, HF antenna that
> actually performs well.

So far, I've been unsucessful in finding something that works well at home, though I do admit I haven't tried the ATAS-100 anywhere but on the car. I've heard very good things about the Force 12 Sigma-5 antenna (vertical dipole) on 20-10 that I went ahead and ordered one a week or so ago. I also placed an order for 40 and 80 meter Isotrons, which I've also heard good things about.

> I bought a MFJ-1622 apartment antenna. I am not impressed with its
> performance. MFJ says that it works well on all bands from 2 meter to
> 40 meter. That's not true.

I haven't been all that impressed with most of MFJ's stuff. I've heard mixed things about their "Super Hi-Q Loop".

Before I buy anything, especially an antenna, I check the eHam.net reviews (http://www.eham.net/reviews/). Since they are user submitted, you get the good, the bad, and the ugly...

> The July QST had some plans for a nice portable HF... has anyone tried
> that?

It's a center-loaded vertical about 12' high. It should work rather nicely, provided you have a decent ground radial system.

My guess is that you could probably make a 3 element beam from it,
assuming that you could get the elements to hold together. (Does it
have hollow elements, or solid rod elements?)

Best way is to sell it (assuming it works and is in decent shape) and
buy a decent 6m antenna. The Cushcraft A50-3S is $100, and will probably
work better than what you could make from the 13B2.

You didn't say the application... mobile, portable, and "cliff dweller" (apartment patio/balcony) are all very different, and have very different "best" solutions.

If you are like me and are looking for apartment solutions, try to find something that isn't dependent on a ground (all your options listed, except for the Buddipole, are highly ground dependent). Quite a few people like the Hamsticks, especially in a dipole configuration.

3405. Question on Tuning Discone To TX on Aviation Band

Newsgroup: rec.radio.amateur.antenna
Date: 2002-08-20 05:22:05 UTC
From: mrcole100@aol.com
Message-ID: <403fdf8.0208192122.502185a1@posting.google.com>
Source record: 136346

I'm interested in determining the best way to tune a discone to transmit optimally on the aviation band. My understanding is that a quarter-inch radiator tuned to 123 MHz should be about 23 inches. Would the tuning be accomplished by adjusting the length of the discone whip, or is it more complicated than that? Also, would that length be measured to the top of the tuning coil or would it include the length of the tuning coil? I plan on purchasing a SWR meter to make this more precise, but wanted to see if it was possible using this method to get closer to the optimal length. The current length of the whip is about 28 inches from the tip of the whip to the top of the loading coil, which I would think is not optimal for the band. Thanks in advance.

Dave

> megawatts what happens to all the extra power?

The additional 10 MW is not created. The new generator is brought up
to speed and frequency/voltage matched to the network. It is then switched
on-line, at which point the current generation capability is there if the
the excitation is turned up.

So the generator is initially just free wheeling (so to speak) and not
producing power. The excitation is increased so that generator starts to
share the current demand - which at the same time reduces the load on the
other generators on the network.

Once the loads are balanced (proportioned out between the generators
based on each generators current capability), the regulation can be
turned over to the automatic circuitry. Now, if the demand increases,
there will be a voltage sag - so the circuitry will increase the
excitation of all the generators and they produce more power. If the
demand decreases, there is an overvoltage situation and the excitation
to the generators is reduced.

These days, the complete startup/shutdown of a generator may be totally
automated. There is no reason why it couldn't be done.

> Am I required to turn on more lights in my house to absorb some of the
> extra power that is being forced into the line?

No, see above.

> Unless there is a very unusual situation I would expect the power
> "forced" into the line under your scenario to be exactly equal to the
> demand.

Yep, although the voltage does vary a bit. Note that the standard for
utility power is "nominal". There is a range of acceptable voltages.

If the load (current demand) becomes significantly higher than what can
be produced by the generators, then there is a serious voltage sag. The
result is termed a "brownout". This can progress to a "blackout" if not
corrected quickly enough - or if the sag becomes bad enough.

> Where did the 200 watts go?

No. Assuming lossless cable, the power traveling through the cable may
well be as much as 200 watts - with none of it being absorbed by the cable.
All the power being generated by the transmitters is then being absorbed
by those transmitters. More than likely, the transmitters will fail very
quickly.

"Pending patents" provide no protection for the inventor.

The only patent I have seen of yours only covers claimed methods of tuning
so-called fractal antennas. As such, it does not keep others from experiments
with fractals - even for commercial purposes.

Even if you could get a patent on design of fractal antennas, highly
unlikely, as the idea is rather obvious, the best you would be able to
do would be to patent certain specific designs - or innovative techniques
of construction.

It depends on what you mean by "small airport".

I used to fly out of a small airport. There were three tall commercial
radio towers only 300 ft or so off to the side of the main runway. I
forget the height of the towers, but they were well over 200 feet tall.

The airport was there long before the towers were erected.

Hi Dave,

I presume your discone is one similar to the Radio Shack model;
especially when you mention the whip. The whip is an extension to
operate at 6M and is outside the standard design for discones.

Simply measure the skirt of the discone (the radials that slope down).
How long is any radial? Longer or about 23 inches? (probably) If
so, it well load up fine and act like any quarter wave vertical (with
a set of radials). Now, if any quarter wave vertical does not work
all that well, then neither will the discone. There is nothing to
really optimize a discone for except drivepoint impedance which at the
high end is dominated by the feed gap.

> having some super hot days here in NJ so I can't get up onto the roof right
> now.

Some thoughts:

Have you verified that the repeater is operating normally?

You noted that receive is down, but didn't comment on tx performance!

Have you verified that the antenna and cable installation are not faulty
(bad connections, excessive loss)?

S meters on FM sets are rarely calibrated according to any pseudo
standard. The situation you describe might well be 8uV (S7) to 1uV
(S0)... don't assume anything like 6dB / S point.

You may just have located the antenna in a node of the standing wave
pattern in space, though the dead spot you describe does seem a bit
deep. Have you tried moving the antenna a little and observing the
effect on the weak repeater?

Discones, being broadbanded, are more likely to contribute to desensing
of a receiver with poor IMD performance / inadequate front end
selectivity (ie most equipment designed for the ham market where
software features are generally valued more than receiver performance -
if manufacturers got it right). Desense would not affect tx performance.

You may have excessive coupling / detuning with the other antennas. I
would not locate the discone with less than a quarter wave vertical
spacing between the lower end of the skirt and the yagi at the lowest
frequency (so if that was 50MHz, use at least 1.5m (5'). Comparitive
VSWR measurement before / after might reveal apparent change in the load
impedance.

Even 40 feet of 45G needs to be guyed - if your local basic wind speed rating is 70 mph with no icing. For 70 ft, you need at two sets of guys. The guy anchor points are at least 56 feet from the tower - for 3 guys per set.

If you want it strong, then you will have to use the specs for 110 mph winds - or even higher. These require the same anchor distances and number. But the square foot antenna rating decreases. For 110 mph winds, the allowable is less than 10 square feet for round tubing - much less for flat or rectangular tubing.

Get the Rohn documentation. It is well worth it.

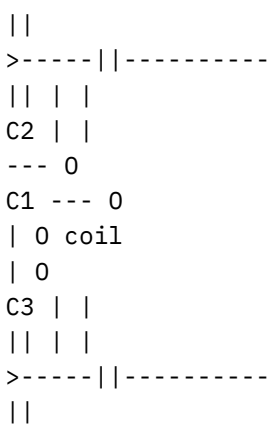
3417. NMR coil detunes

Newsgroup: rec.radio.amateur.antenna
Date: 2002-08-20 11:19:23 UTC
From: Martin Kavec <martin.kavec@uku.fi>
Message-ID: <ajt8k2jau1@luotsi.uku.fi>
Source record: 136358
Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.homebrew,sci.techniques.mag-resonance

Hello everybody,

I would like to ask you for explanation and possible solution for a p
roblem I face.
I made following brand new NMR coil:



This is a simple surface coil (loop of wire, since I post to a groups
where they might not be aware of this term) 3 cm diameter, made of round
copper wire (1.3mm diameter) and the capacitors are high quality nonma
gnetic trimmers made by Voltronics. The coil is powered by coaxial
cable (MIL-17/RG400) 50Ohm cable. The tune frequency is 200MHz. The coil
tunes fine and matches fine (though I don't know exactly on res
onance resistance).
The problem is that the coil detunes as soon as I move the coaxial cable.
Not a problem but a seek for information: I read that additional cap
acitor parallel to the coil wire, attached directly on the wire improves th
e coil homogeneity and the quality. How can I calculate the value of
such a capacitor.

Thank you and I appreciate any kind of help.

I have a chart from Rohn titled "Self-Supporting Towers - Allowable Antenna Areas (Sq.Ft.)". For instance, a self-supporting 45G tower of 40 feet will tolerate 5.1 sq.ft. of antenna in 70mph winds with no ice. With 1/2" of ice, it will tolerate zero sq.ft. of antenna, i.e. it will only tolerate itself. Take the winds up to 80mph and it may fall down.

This chart is Rohn drawing number A871266 RI dated 9-24-87. Unfortunately all the heights above 40 feet are torn off and missing.

I forgot to say that the absolute limit for self-supporting Rohn 45G
towers is 45 feet. At 45 feet with 70mph winds and NO ice, it will
tolerate a 2.3 sq.ft. antenna. Note: Ice and 70mph winds are not
allowed at the same time.

I have a 30 foot Rohn 25G self-supporting tower with a 20m rotatable
dipole on it.

Hi

I'm looking for a "good" discone antenna for a AR 5000.

From now, I do have 3 candidates :

DA 3000 from AOR up to 2 GHz
AH 7000 from Icom up to 1.3 GHz
Discone from Diamond up to 1 GHz

The 3 antennas seem to be very similar ...

... and I do have the feeling that the choice is probably dictated
by the quality of fabrication and materials.

Any field experiences ?

Note : I'm only interest in the performance in RX in the segment 150
MHz to 1.8 GHz.

Thanks for your help

Hi Dave,

True discones don't have whips. The disc is a counterpoise for the broad band cone.

This whip portion you discuss replaces the disc and uses the cone as the second half of a dipole configuration. The cone does some degree of loading, so the whip can be --very roughly-- 10-15% shorter than a quarter wave. However, the antenna will be reasonably broad band anyway (like that) so you probably won't get any true advantage if the whip is in th ballpark. This is assuming a roughly 1/4 wave high cone.

If the cone is less than about 3/12 of a wave in height at that frequency then the whip will have to be longer than a 1/4 wave but, again, the dipole (which is what it is) will be fairly broadband as it is. You should be able to just leave it.

Bill, N3WK wrote:
"I am not sure what you`re trying to say here."

Superposition is a tool for simplifying circuit analysis. A simple application is one in which one source drives a current from a to b, and another source drives a current from b to a. Superposition allows you to take the difference in the currents and use it in Ohm`s law to calculate the voltage between a and b. Superposition just allowed you to calculate the currents from each source one at a time.

Knowing the a to b voltage and current in a resistor allows you to take their product as the power in the resistor. Superposition is only a step in a journey.

To find power delivered to a load by coax, you have an advantage of knowing the voltage to current ratio the waves see. It is the Zo of the coax. This fixes the voltage to current ratio of the forward and reflected waves. This has nothing to do with SWR in most cases.

SWR is likely to affect the load seen by a transmitter, but does not affect the impedance seen by the forward and reflected waves in most cases. The wave voltage to current ratio is simply Zo, coming or going.

Zo is controlled by construction of the line. This simplifies the math. It allows power to be added and subtracted.

Math is also simplified in the electric power company lines. Their voltage is usually held constant. This simplifies the math. It allows power to be added and subtracted. P=EI, and If E is a constant, P is proportional to I. Generators share loads in proportion to their current contributions.

Knowing how to use superposition is not necessary to calculate power flow in a transmission line. Just follow Bird`s instruction. Power to the load is forward power minus the reflected power.

BNest regards, Richard Harrison, KB5WZI

Based on sales and market size, I think Cushcraft is just reducing the size
of the product line.

You will still see many products for the commercial market (especially
VHF/UHF/SHF) that will be completely usable in the amateur allocations.

The number of new antennas for HF (big beams) and towers are decreasing -
thanks in no small part to the community antenna and zoning restrictions
around the country. The "disguise" antenna business is doing quite well
(for both commercial and amateur)

In my most recent posting I wrote:
"P=EI, and if E is a constant, P is proportional to I."

In retrospect, some reader may say, this is a-c so P=EI cos theta. My simple assumption is that theta is zero, the power factor has been corrected, and cos theta is 1. I said powers could be added and subtracted, not apparent powers.

Best Regards, Richard Harrison, KB5WZI

Richard,

The discone is like the RS version and the cone radials measure about 31 inches, which is significantly longer than 23 inches. So what I think you're saying is that adjusting the length of the whip should have no bearing on the aviation band since it's only use is to extend performance for lower frequencies, and I'm already as tuned as I'm going to get. Thanks for the help.

Dave

We have a repeater in the presence of 250 Kw UHF TV transmitter. We are not experiencing any pronounced problems with our 2m repeater @ 300', but wanted to take all precautions. My questions:

1. What would be the proper toroid material and who to order it from?

2. What should be choked?

a. Main feedline to the antenna (at the duplexer, I would gather)?
b. Rx and Tx cables from the duplexer (at the input to the Rx and ouput of Tx) ?
c. Power cables to the repeater (as they enter the repeater case)?

TIA

Source record: 136271

Hi,

Thanks everyone for allthe help these past few weeks. getting back into the hobby after retiring, and
it seems like one question leads to many more. really appreciate all the help from everyone.

This is a really embarrasing one:

Was looking at the discone (receive only) I placed up in my attic some 20 years ago for receiving the over 30 MHz stuff.

Notice (now) that the three radial arms are connected in common to a plate, that's directly screwed to the metal
mast.

But I grounded the mast to a local waterpipe in the attic. No idea anymore why i did this, but "presumably"
the instructions said to do so?

So, let me ask-

Should this plate with the 3 arms be grounded up there to a water pipe ground at all?

Or, should the ONLY grounding be thru the coax shield back at the receiver end, and the mast assembly left ungrounded?

Really wondering now if I did it right all those years ago. Antenna has "worked," but never great.

Much thanks,
Bob

Hi Dave,

You might want to visit:
http://www.qsl.net/kb7qhc/antenna/Discone/discone.htm
where I review how the variation of the skirt angle impacts the
drivepoint impedance across a wide frequency (it matters little if the
frequencies happen to be yours). It also employs the Smith Chart to
correlate this data.

3434. Magnetic Loop ALA330 useful indoor ?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-08-20 20:20:56 UTC
From: Thierry Lombry <lombryt@hotmail.com>
Message-ID: <3d62a4b6_2@news.vo.lu>
Source record: 136275

Hi,
Living in an appartment in LX, 2d floor, I tied a long wire from the appartment to the end of my garden (about 10m across the appartment + 15m tied ◆ 45◆ up to a fence, see pic on http://www.astrosurf.com/lombry/qsl-longwire2.htm mid op page).
This wire captures a lot of severe QRM (a strong background noise at S5-7 on most HF bands) probably generated in the neighborhood), a QRM I do not experiment in my second QTH, an individual house located on top of hills in Belgium, at 100m from the nearest neighboor, where I installed a 40m longwire tied 3m high that gives excellent results.

So i would like to know if using another type of antenna, for example a magnetic loop like the ALA-330 (detail on http://www.wellbrook.uk.com/ALA330.html) I could resolve my QRM problem in LX and improve Q signals. Although the manufacturer recommands to place the M.L. 5m away from any building, I have to install it indoor, in the room located garden side.
Do you think such installation could give me better results that my current (short) long wire ?

The other solution will be to install a MFJ Interference & noise canceler. But I think that the new antenna will improve the strengh of signals and will reduce QRM by its design.

Thanks for comments.

Actually, according to Johnson's derivation of eq. 4.23, the total steady state forward voltage is given by the sum of the forward source voltage [Eg Zo/(Zo + Zg)] plus all of the re-reflected voltages developed at the generator. Eq. 4.23 is an equation for the total voltage at any point x on the line, where this total voltage is given by the sum of the total forward voltage + the total rearward voltage. Johnson clearly states that the total forward voltage is given by the sum of all the forward voltage components and that the total rearward voltage is given by the sum of all the rearward voltage components. He does not mention power addition in this section.

You might also want to check the equation you gave above for forward voltage. I agree that the forward power equals delivered power (your source power) times 1/(1 - rho^2) as this is derived from the simple relationship Pdel = Pfwd - Pref. However, I'm not sure that Vfwd = Vtot Sqrt[(1/1-rho^2)]. While the forward power is greater than the delivered power, the total forward voltage is not always greater than the total voltage in the line as your equation would require.

>I'm interested in determining the best way to tune a discone to transmit optimally on the aviation band.<

My Diamond discone--same as RS--has no top section installed and it exhibits excellent SWR accross the entire aviation band (just checked it with my analyzer). Should be no problem transmitting through it whatsoever.

Let's be sure everyone understands there's no such thing as negative
power. The sign on the power (energy flow past a point) is simply a
convention indicating the direction of energy flow. Toward the load
is normally the plus direction and away from the load is normally
the negative direction. Forward power is toward the load. Reflected
power is away from the load. Forward power minus reflected power
equals power delivered to the load.

I've noticed at vhf/uhf a lot of commercial companies simply coil up a
few turns of coax directly under the antenna.

There is indeed negative power. Please read my recent posting on instantaneous and average power. It explains that when a load is anything except a pure resistance, the power is positive for part of its cycle (frequency twice that of V and I) and negative for the remainder. If you should choose to define positive current flow in the other direction, the power waveform simply flips over, and it's still positive for part of the cycle and negative for the remainder. You can see a graph of this in most circuits textbooks.

Even average power can be negative. Consider a 5 volt DC source in series with a 3 volt DC source, but connected so the voltages subtract. Connect a 2 ohm load to the pair. You can easily calculate that the current is one ampere, the power delivered by the 5 volt source is 5 watts, the power delivered by the 3 volt source is -3 watts, and the load resistor dissipates 5 - 3 = 2 watts. The power dissipated in the load equals the sum of the powers delivered by the sources, as it should be.

You'll calculate a negative power when dealing with some antenna arrays, where an element consumes a negative power. That is, it delivers power to the feed system rather than consuming it from the feed system.

Source record: 136284

I got down to brass tacks today. I made an appointment with a Texas A&M EE professor, an expert in electromagnetics. I presented him with the following example that we have been discussing:

100w XMTR---50 ohm feedline---+---1/2WL 150 ohm feedline---50 ohm load

He agreed that Rho at the 50/150 impedance discontinuity is 0.5 but he said there are no steady-state reflections on the 50 ohm feedline from that impedance discontinuity. I said, "How can there not be any reflections from a Rho = 0.5 impedance discontinuity?" He said, "There's just not any." I wasted an hour of my time trying to explain wave cancellation to him. He said there was nothing to be canceled. He has apparently programmed himself to believe that reflections don't occur at all at the 50 ohm virtual impedance.

Seems to me, guys like him have abandoned reality in favor of their math models.

So here's a question for the gurus. When non-glare glass does its thing, where do the photons go that were canceled? The energy in photons can be turned into heat but it is my understanding that the energy in photons cannot simply disappear. Seems to me, the cancellation of the glare must make the picture either a little brighter or a little hotter.

This doesn't contradict what I said, Roy. The sign indicates the
direction of positive energy flow, NOT that the energy is negative.
The -3 watts simply indicates that the battery is being charged
instead of being discharged.

You could feed two dipoles from the same coax if you arrange them 90 degrees apart to minimize interactions. I've done it with 40m/80m combinations. The frequencies are farther apart at 40/80, but it should be worth a try at 17/20m.

Good luck, wire is cheap...experiment!!

This one (and variations) has been told so many times that no one ever
questions it. I see two people, you and Cecil, quoting this but I
don't recall anyone ever verifying it. I'm extremely skeptical that
power transmission could be so simplistic. But I'm willing to learn,
so please give me the name of a paper or text where the simple
addition of power from multiple generators is explained.

I haven't mastered anything, Richard, I'm still asking questions. Lots of pieces just don't fit. Walter Maxwell gets raked over the coals for suggesting a virtual impedance can cause a reflection. Steve is allowed to use a reflection coefficient of 0.5 to calculate an un-reflected power when there isn't any reflected power. What gives?

In the following example, are there any reflections? If so, where are the reflections originating? The TV signal generator has a circulator that dissipates all reflections seen by the generator, i.e. there are no re-reflections from the generator.

TV signal---75 ohm coax---+---1/4WL shorted stub---
generator |
High Impedance TV Receiver

The 1/4WL shorted stub is providing a virtual open circuit. If a virtual impedance can cause things to happen, there shouldn't be any ghosting. Will there be any ghosting?

Yep, they work that way because they are really two 1/4WL verticals
spaced 1/2WL apart fed at their tops. The current maximum points
are at the highest points on the antenna which is a good thing.

Roy, W7EL wrote:
"There is indeed negative power."

At the end of a transmission line, when the load impedance is infinite (an open circuit) the reflection coefficient is 1 on an angle of zero. The incident and reflected voltages are in-phase and the load voltage is doubled. The currents, incident and reflected, are equal like the voltages, but are 180-degrees out of phase so they cancel.

From the extreme of an open circuit on the transmission line to a less extreme condition we can gather that when the load resistance is too high to match Zo of the transmission line but is finite, the behavior is similar but less severe. The sum of the forward and reflected voltages are in phase but the magnitude of their sum is less than double the incident voltage. The reflected current is phase reversed from the incident current but of lesser magnitude than the incident current, so the currents don`t cancel at the load.

If the load resistance is less than Zo, phase of the reflected voltage is reversed. Phase of the reflected current is unchanged.

When power is defined as the rate at which power is transferred past a point, reversal of its direction is considered as a negative.

A reflection from a mismatched load results in a 180-degree phase change of either the voltage or current, but not both. So one might say a positive voltage times a negative current is a "negative power" because it reverses the direction of power flow.

Note that this negative multiplication product does not take place during the alternations of an a-c voltage cycle. On the positive alternation you have a positive voltage times a positive current. On the negative alternation you have a negative voltage times a negative current and this product is positive just like a positive times a positive.

There are two power pulses during an a-c voltage cycle and both of them are positive.

Best regards, Richard Harrison, KB5WZI

Mobile or base operation? And how well do you want it to perform?

I have a Yaesu FT-100D that I use mobile on those bands. For 6 and 10 meters ssb and fm I use Hamsticks with a quick disconnect so I can switch between them. They do a decent job, but I'm not aware of any antenna that would cover both bands due to the frequencies involved.

For 2/440 fm I use a dual band antenna. It is a compromise, but works OK for me - local repeaters and limited simplex range.

Good luck and 73,

CAM, W5DXP wrote:
"Walter Maxwell gets raked over the coals for suggesting a virtual impedance can cause a reflection."

A hybrid ring is often used to connect two transmitters to a common load. Connections from the two transmitters each have two paths to the load port. Signals via both paths for a transmitter are in-phase at the load port.

Signals via both paths between transmitters are out-of-phase at the other transmitter port so they cancel. It`s a matter of producing a virtual short or open at each transmitter port for energy from the other transmitter but not for the energy output of that port`s transmitter. The energy isn`t abolished. It ultimately is consumed by the load.

The virtual impedance to each other`s energies isolates the transmitters from each other. The rejections are almost total reflections.

Best regards, Richard Harrison, KB5WZI

If you can't see it you can't explain it.
Waves, photons etc are explained by theories. So what is a theory?
It's a conclusion about the behavior of something based on our experiences.
This does not mean that it's correct or wrong but it is they way we perceive
it.

Waves etc are still black magic. No one really knows how they work and if
anyone says they do then they are a liar!

3467. Re: Question on Tuning Discone To TX on Aviation Band

Newsgroup: rec.radio.amateur.antenna
Date: 2002-08-21 03:24:19 UTC
From: mrcole100@aol.com
Message-ID: <403fdf8.0208201924.34f3b5fd@posting.google.com>
Source record: 136308

Thanks to Richard, Chip, and Rick for the help. I have an ICOM A22, which you guys probably know is an airband transceiver, connected to the discone through about 20 feet of RG-58. The discone is sitting on my balcony because I live in an apartment and I'm moving in the coming week, so it didn't make any sense to mount it. I live about 15 miles from Philly International and about 8 miles from Northeast Philly Airport. I can hear Northeast Tower clear as day and I can also hear both Philly Tower and Philly Approach when the squelch isn't set too high. My ability to pull in the Philly Tower and Approach end of the conversation surprised me. I also heard my instructor last night as he was flying in the pattern at my airport. I was actually able to talk to him for a few minutes. My airport is about 10 miles from my house. Other than raising the antenna I don't know whether I can improve my range. Would using RG-8 make a significant difference in performance? Thanks again.

Actually as I'm writing this I think I'm picking up transmissions from planes from planes landing at airports outside NYC, which is about 80 miles from me.

Hm, that's an interesting point of view. Because electrons are negative, there's no such thing as positive charge, so there's no such thing as positive current. It's really current, which can only be negative, moving in a negative direction.

You're much more fond of making such distinctions than I, so I'll leave them to you. I'm comfortable with calling a negative value of P a negative power, but whatever floats your boat. Just so long as you, and your readers, understand what you're talking about. Just remember, now. No positive current, either.

PROLOGUE

Fuck off Phar-Lap fake name wimp shit. Aaron Kim is right. The two special white stones, one dated Carboniferous, the other dated Cretaceous, in the two bows of Joseph Smith, Jr., are well known by the micropaleontologists of London's Natural History Museum. And dick suck, the golden plates of Joseph Smith, Jr. have already been geophysically located by Denoco Inc. of Texas geophysicists at Bratton Camp (Westbury) White Horse Eye. The two bows containing these two special white stones of Caddo Indian Tommyhawk are well known and published, well protected and well preserved, in Texas, dumbass. And Sun Angel Moroni's 16 Stonehenge Carboniferous and Cretaceous white stone samples were divided (melted)into 24 separate specimens embedded in said two bow arrows of Caddo Indian Tommyhawk. So fuck off because Aaron Kim is right. You don't know a fucking thing about this...

Now's the time! BEFORE they are stolen by Osama bin Laden's London Cells on September 11, 2002! I am going to cause, with or without anyone's help, The Natural History Museum of London to TELL THE FUCKING TRUTH about Doctor Garry Whilhelm Denke's, Joseph Smith, Junior's, Sister Amelia Denke's, and Tommy (Tommyhawk) Littlepage's white Mississippian (Lower Carboniferous) geologic age stones (of

various sizes, shapes, textures, hardnesses, and source areas) in the Heel Stone ditch original backfill, which circles MY ark of MY testimony location, and the white Upper Chalk (Late Cretaceous) geologic age stones. Their (Natural History Museum's) micropaleontologists addresses and phone numbers are at URL: http://www.nhm.ac.uk/ They all know about this. THEY are trying to THIEF MY ARTIFACTS.

> I looked (searched the I.) for info on the special white stones of Caddo
> Indian Tommyhawk but couldn't find any. Obviously you know more than most on
> this subject and your background points to some possible knowledge that may
> not be readily available to all who are interested.

My three (3) sources of samples of the two (2) different types of white stones at Stonehenge and my three (3) sources of samples of the two (2) different types of white stones at Bratton (Westbury) White Horse Eye, United Kingdom, said White Horse Eye also being filled with the white Ancient Mississippian (Lower Carboniferous) geologic age stones (of various sizes, shapes, textures, hardnesses, and source areas), are discussed in brief below (I'm trying to just publish enough information to cause excavation by the right people, e.g., NOT Osama bin Laden's London Cells), which is why I have not downloaded all of my B.C. and A.D. tangible information onto a www site.

> Can you refer me to some credible information, your own site perhaps.

CALL THOSE LYING FUCKING WHORES! I gave you the phone number!

> Thanks for your time.

You're welcome.

FIRST STONES BROUGHT TO STONEHENGE: THE MISSISSIPPIAN AGE WHITE ELDERS

From: Garry Denke (GarryDenke@USA.Net)

To: Doug Weller (dweller@ramtops.demon.co.uk)

MESSAGE:

Firstly, nice try Douglas Weller but it is now known and published that Garry Denke is a degreed geologist who graduated from Arizona State University in 1977, in the top ten (10) of the ASU geology department class, that same Garry W. Denke who is currently President of Denoco Inc. of Texas, an active State of Texas corporation currently exploring for natural gas in East Texas, currently operating oil leases and wells in North Texas, and currently certified and bonded by the Railroad Commission of Texas http://www.rrc.state.tx.us, which you, Mark Purnell, Giles Miller, et al, have today again verified under the same RRC website. Secondly, as you know Douglas Weller, it is now known and published that United States geologist Garry Denke's ancestor, the German historian, antiquarian, and Doctor Garry Whilhelm Denke (b. April 19, 1622, Baden, Schwarzwald, Germany - d. February 19, 1699, Caddo confederacies, Texas), first discovered Mississippian geologic age Waulsort stones in the Waulsort (now called Aubrey) Holes and Hell (now called Heel) Stone circular ditch at Stonehenge, United Kingdom, in 1656. Thirdly, as you now know, Garry Denke's German to English translations have been corrected and edited herein from the previous authored texts of Garry Denke, as rewritten and verified by the Erodelphian Literary Society of Sigma Chi Fraternity, Arizona State University, North Texas Branch (August 9, 2002).

The authors of "Stonehenge in its landscape, twentieth-century excavations", English Heritage, 1995, referenced Professor Richard Atkinson's "hard white chalk rubble" excavated in the 1950's as being the original backfill of the Heelstone ditch at Stonehenge (Pages 171, 174). Their eolian Cretaceous geologic age "chalk" report covering this backfill was, and still is, a geological and micropaleontological lie. The Heelstone ditch, once known as Hell Stone ditch, and its backfill of Mississippian (Tournaisian) Waulsortian facies rocks (Waulsort stones) were first noticed to be different from the Cretaceous age white chalk common to Stonehenge, by German historian, antiquarian, and Doctor Garry Whilhelm Denke (b. April 19, 1622, Baden, Schwarzwald, Germany - d. February 19, 1699, Caddo confederacies, Texas), who using his medical magnifying glass compared identical physical properties of shape, texture, and hardness, and identical biological properties of fossilized creatures to Mississippian limestone common to the village of Waulsort, south of Namur, Dinant Basin, Belgium. Doctor Garry Denke's catalogued archived collection of samples from each of the Waulsort Holes and the Hell Stone ditch were preserved by the Caddo Indian (Tommy "Tommyhawk" Littlepage) of Young County, Texas, who in 1979 at the Dallas Production, Inc. #1 Littlepage Oil Well transferred said collection guardianship to Garry Denke.

Prior to the Erodelphian Literary Society preliminary 1976 Arizona State University micropaleontology of Professor Atkinson's "hard white chalk rubble" showing this Heelstone ditch backfill as not local Senonian (Late Cretaceous) Upper Chalk native to Stonehenge, but the elder Arundian (Lower Carboniferous) High Tor Limestone transported by the Neolithic builders from the Pembroke area, South Wales Coast. Sister Amelia Denke, kindergarten schoolmaster of Drums Elementary School, Drums, Pennsylvania, acquired labeled U.K./U.S Mail gathered samples of the Aubrey Holes (Waulsort Holes), Heel Stone (Hell Stone) ditch backfill, and the common Stonehenge chalk from the British antiquarian Colonel Hawley in 1961. Sister Amelia Denke who was in possession of the Denke Family Bible at the Drums Elementary School taught the Revelation of Jesus Christ's Sarsen stone and its four beasts (pictured at URL below), twenty and four white elders (microfossils) creatures, and ten thousand times ten thousand and thousands of thousands of white Cretaceous coccoliths (nannoplankton) creatures to Garry Denke, president of Sister Amelia's kindergarten class, who in turn passed the knowledge of the pictured big beast (Daniel's bear) and four beasts (lion head, ox calf head, wounded man face, USA's flying eagle), 24 white elder creatures, and 10,000 x 10,000 and 1000s of 1000s white coccolith creatures to his classmates. In 1970, at Our Lady of Grace Junior High School, in 1973 at Hazleton High School, and in 1974 at Indiana University of Pennsylvania, said elders (microfossils) were classified as shown in Table 1 below, under Sister Amelia's 1961 Collection.

[Table 1. Courtesy of Garry W. Denke]

From 1979 through 1985, Arizona State University, Sigma Chi Fraternity, and Denoco Inc. of Texas micropaleontologists verified and confirmed through an arduous comparison study financed with private funds by Garry W. Denke and Denoco Inc. of Texas, that said Sister Amelia Denke's Drums Elementary School kindergarten catalogued archived collection of the above identified white Mississippian microfossils were identical to said Doctor Garry Denke's Tommy "Tommyhawk" Littlepage catalogued archived collection of the above identified Mississippian microfossils shown in Table 1 above. In 1990, Eldorado Oil and Gas, Inc. made an independent examination by electron microscope of all the samples gathered by Doctor Garry Denke in 1656 and Colonel Hawley in 1961 and determined that there were no nannoplankton coccoliths in the stones from the Aubrey Holes and Heelstone ditch backfill. Furthermore, the samples of the white Cretaceous chalk from both the 1656 and 1961 collections at Stonehenge were identical, but when compared to Doctor Garry Denke's Westbury White Horse Eye collection of 1656, it was discovered that the Cretaceous nannoplankton coccoliths were more similar to the Cretaceous Austin Chalk coccoliths of East Texas Field which crops out in Plano, Texas. Each of the above Mississippian archived microfossils, with catalogue, were U.S. certified mailed in 1994 to all seven of the Silent Partner Owners listed in Table 2 below.

Doctor Garry Denke's 1656 and Sister Amelia Denke's 1961 collections of the first stones of Stonehenge from inside and outside the Aubrey Holes and Heelstone ditch, and Doctor Garry Denke's collections of stones inside and outside the Bratton Camp White Horse Eye http://www.wiltshirewhitehorses.org.uk/westbury.html Westbury White Horse Eye, with catalogues, are archived in cased glass at the RRC Texas Oil Field in Baylor County, G'S US. Glass encasement was performed on December 1, 1993 by Fraco Services, Inc. of Holliday, Texas. The RRC website URL is http://www.rrc.state.tx.us/ and there is no entrance fee to see the oilfield of G'S US. Currrently under study at the laboratories of Denoco Inc. of Texas are the micropaleontological archived catalogued collections from 42 Waulsortian facies collection sites located in the Dinant Basin, south of Namur, Belgium, Pembroke, Derbyshire, the Pennines of England and Ireland, central France, Upper Banff Formation of Grotto Mountain, Alberta, Big Snowy Mountains of Montana, Boone Formation of Ozark Dome, Oklahoma, Sacramento Mountains of New Mexico, and the Llano Uplift of Texas, whereat the white Mississippian Chappel Reef limestone of RRC Texas Oil Field in Archer County, Revelation, crops out. Garry Denke, Geologist EIN'S TIN: 75-2554014 conclusion from his detailed micropaleontological comparison of the 42 collection sites located in the above listed areas shows all twenty-four (24) Mississippian elders named in Table 1 above being identical from all areas studied.

Call for papers.

>

This is only true if the load is a pure resistance. The reflected voltage equals the forward voltage times the voltage reflection coefficient. The reflected current equals the forward current times the negative of the voltage reflection coefficient. The voltage reflection coefficient is (Zl - Z0) / (Zl + Z0). The magnitude of this complex quantity can be anywhere from zero to one, and it can have any angle. So the reflected voltage and current can have any angle relative to the forward voltage and current, not just 0 or 180 degrees. Assuming a real Z0, the forward voltage and current will be in phase, so the reflected voltage and current will have a relative phase angle of minus two times the angle of the reflection coefficient. This can be any angle, depending on the relationship between Z0 and Zl.

Sigh. This is true only if the load is purely resistive.

It's pretty obvious that my recent posting of the topic was either ignored, not understood, or disbelieved. I've done my best, so all I can do in addition is refer you to a circuits textbook. If you have either Van Valkenburg or Pearson and Maler, I can direct you to the appropriate page.

We can blame Benjamin Franklin for that one. When I was at Texas A&M in the late 50's, I was taught positive current flow but was warned that the military used the more correct electron flow along with left hand rules. In transistor theory, I learned about hole flow.

Point is that the kind of power we are talking about is joules passing a point in one second. There's just not any negative joules in our transmission lines. Joules flowing past a point on their way to the load are by convention defined to be positive power. Joules flowing past that point on their way to the source have to be satisfied with the opposite of that convention, i.e. negative power. But the negative is all in the direction, not in the joules.

3474. Re: Air-Wound Balun Design Info??

Newsgroup: rec.radio.amateur.antenna
Date: 2002-08-21 04:06:54 UTC
From: n2ey@aol.com
Message-ID: <20020821000654.25779.00000094@mb-cb.aol.com>
Source record: 136315

In article <d22b54c3.0208201424.30a5aa7d@posting.google.com>, kelly@dvol.com (Brian Kelly) writes:

>Preferably 7.0 thru 28.1 Mhz but 7.0 thru 21.1 would be fine.

Three solutions:

1) Bead balun. Probably the lightest weight and if you use decent beads they won't saturate. But you want air, so....

2) Scale down the RG-213-on-4-inch pipe idea. Use 1-1/2 or 1-1/4 inch PVC pipe and RG-58 with a stranded center conductor. 11 or 12 turns close-wound in a single layer should be adequate to give 500 ohms reactance at 7 MHz. Diameter about two inches, length about 3-1/2 inches, weight a few ounces.

3) Trifilar-wind #14 speaker wire in a manner similar to 2). (This is the Orr design).

Now whether all this is worthwhile for a simple dipole is another question. Is this balun supposed to o at the dipole feedpoint? If so, I say forget it and just attach the coax.

With a beam you do NOT want any feedline radiation at all, for obvious reasons. But with a dipole, a little feedline radiation (if it happens at all) usually won't hurt anything.

For my lightweight portable antennas, I use 8-10 turns of RG-174 on a one inch or so O.D. toroid core of type 43 or one of the 70 series ferrites. The latter will give more impedance over the HF range. I also use this on my home antennas, and have had no trouble at power levels up to 300 watts or so.

You could wind the coax into an air-core choke following the procedure in the ARRL Handbook or Antenna Book (except that you should wind the coil like a coil of rope or an extension cord, not carefully spaced as mistakenly described in recent Antenna Books). One made from RG-174 using the RG-58 dimensions would be adequate. But this would be bulkier than the toroid solution unless you rewound it each time you used the antenna. It can also have a lot of wind resistance and be subject to snagging in trees and brush.

For those fussing about what a balun is, I suggest reading "Baluns: What They Are and How They Do It", in the ARRL Antenna Compendium, Vol. 1.

Do you mean that you can't use the equations in _Reference Data for Radio Engineers_ or the text of your choice to calculate exactly the forward, reverse, and total voltages and currents on each line segment and at the input and output?

If not, I suggest it as a good intellectual exercise, and not at all difficult for someone with college freshman engineering math skills. When you're done, you'll almost certainly have a much better understanding of how transmissions line work. And you're bound to get better answers than you will by posting the questions on this newsgroup, and probably better than asking most professors.

You did go to Texas A & M, didn't you?

Food for thought: Forward and reverse power

This essay discusses transmitter models, forward and reverse power, what happens to reverse power when it encounters the source impedance, "mismatch loss", and recovering reverse power with a circulator.

In the following discussion I'm going to assume for simplicity that transmission line loss is zero.

When this is true, the average power furnished by the source (which I'll call the net average power) equals the average power delivered to the load. And previous analysis revealed that when Z0 is purely real, as it is when the line is lossless, we can separate the average power into "forward" and "reverse" components whose difference equals the net average power furnished by the source or delivered to the load. The average forward power can be computed from the forward travelling voltage and current waves, and the average reverse power can be computed from the reverse travelling voltage and current waves.

My commercial amateur HF transceiver is probably typical of modern rigs in that it produces a constant *forward* average power into varying load impedances -- provided the impedance isn't extreme enough to cause the rig to severely cut back its power output. I could combine the transmitter with a transmatch to make a system that would deliver a constant *net* average power into any load within the adjustment range of the matching network. Of course, the matching network would have to be adjusted each time the load impedance were changed.

It turns out that a linear model of my transmitter (without a transmatch) over its non-shutdown range is very simple -- it's just a voltage source in series with a resistance. This combination produces a constant average forward power into a transmission line connected to any load impedance, if the series resistance equals the characteristic impedance of the line. I'm going to present this without proof, although the calcuation is straightforward from fundamental transmission line equations. Any example you can devise will confirm it holds true.

I make no claim that the model circuit represents what's going on *inside* the transmitter. For one thing, a real transmitter will typically be more efficient than the model. However, if measurements and observations are limited to the outside of the transmitter, the model is very good (within the non-shutdown range). Although a real transmitter won't contain the model's resistance as a resistor, we will take a look at the model resistor's dissipation to see how it interacts with the "reverse" power.

The average forward power fPa fed into a line with (purely real) characteristic impedance R0 by a voltage source of RMS voltage Vrms in series with a resistance R0 is

fPa = Vrms^2 / (4 * R0)

So we can model a 100 watt forward, 50 ohm nominal transmitter as a 141.4 volt (100 * sqrt(2)) RMS voltage source in series with a 50 ohm resistance. If we connect this to a 50 ohm transmission line of any length, we can put on any load impedance we like, INCLUDING A SHORT OR OPEN CIRCUIT, and we'll have 100 watts of average forward power in the 50 ohm line. In terms of the impedance Zi = Ri + jXi looking into the line, and the source resistor and line's (assumed purely real) characteristic impedance of R0,

fPa = Vrms^2 / (4 * R0)

rPa = {Vrms^2 / (4 * R0)} * {[(Ri - R0)^2 + Xi^2)] / (Ri + R0)^2 + Xi^2]}

where fPa and rPa are the average forward and reverse power, respectively. The net average power from the source and into the load Pa = fPa - rPa. Another useful relationship, although it won't be used here, is that rPa/fPa = rho^2, where rho is the magnitude of the reflection coefficient at the load end of the R0 line.

Let's take a look at a few simple cases. Connect the "transmitter" through a half wavelength 50 ohm line to a load. (I'm choosing a half wavelength line just to make the input impedance easy to calculate. The forward and reverse powers are independent of the line length if the line is lossless as it is here.) So Zi = Zl, the load impedance on the far end of the line. Also notice that the forward power doesn't depend at all on Zi, hence Zl, so it will be 100 watts for all the following examples.

If Zl = 50 + j0, a matched load, then from the equation above, rPa = 0. If Zl = 100 + j0, one of the infinite number of possible loads causing a 2:1 SWR on the line, rPa = 11. If Zl = 25 + j0, another 2:1 SWR condition, rPa = 11. Zl = 37 + j28 is yet another (nearly) 2:1 load, and rPa = 11 as it should. It's easy to see that if the load is a pure reactance (Rl = 0), rPa = fPa = 100 watts, and if Rl = 0, rPa = 100 watts. If the load end of the cable is open circuited, Ri = Rl gets very large. Because it's much larger than R0 or Xi, the second bracketed quantity in the rPa equation approaches 1, so again rPa = fPa = 100 watts.

Although I've said that the "transmitter" model doesn't represent the inside of a transmitter, it does represent the inside of a signal generator, which typically does have a physical source resistor. It also represents, well, a voltage source in series with a resistor. Let's take a look at the resistor's dissipation.

Here, we can do a very simple analysis. As seen from the source resistance, the load Zi is simply Zl, since there's no impedance transformation by the half wavelength of transmission line. So the circuit is a simple voltage divider. From this we can do the following

calculations. Il = the current from the source, through the source resistor and through the load. (The current isn't transformed by the half wavelength line either.) With source resistor being R0, Ilrms = Vrms / (R0 + Zl). Power dissipated by R0 =

Pa(R0) = |Ilrms|^2 * R0 = (Vrms^2 * R0) / [(R0 + Rl)^2 + Xl^2]

and the power dissipated by the load =

Pa(Rl) = |Ilrms|^2 * Rl = (Vrms^2 * Rl) / [(R0 + Rl)^2 + Xl^2]

Note that the net average power disspated by the load Pa(R0) equals Pa(tx), the net average power produced by the "transmitter", which equals fPa - rPa. The net average power produced by the "transmitter's" voltage source Pa(src) is this amount plus the amount dissipated in the "transmitter's" source resistance, or Pa(R0) + Pa(Rl). The fraction of the total source power dissipated by the load is, from the above equations, frac Rl = Rl / (R0 + Rl). The fraction of the total power dissipated by the source resistor is frac R0 = R0 / (R0 + Rl).

From this, we can calculate:

Zl fPa rPa Pa(tx) Pa(src) Pa(R0) Pa(Rl) frac R0 frac Rl
50 + j0 100 0 100 200 100 100 0.50 0.50
100 + j0 100 11.1 88.9 133 44.4 88.9 0.33 0.67
25 + j0 100 11.1 88.9 267 178 88.9 0.67 0.33
37 +/-j28(*)100 11.4 88.6 209 120 88.6 0.58 0.42
0 +/-j50 100 100 0 200 200 0 1.00 0
0 +/-j100 100 100 0 80.0 80.0 0 1.00 0
0 + j0 100 100 0 0 0 0 - -
infinite 100 100 0 0 0 0 - -

(*) For any Zl that causes exactly a 2:1 SWR, rPa will equal 11.1 and Pa(Rl) = 88.9. The values shown for 37 +/-j28 are slightly different because this impedance doesn't result in quite exactly a 2:1 SWR.

For the second, third, and fourth entries, the SWR is 2:1. The forward and reverse powers are the same for all three, and the source impedance (50 ohms) is the same for all the above cases. So here we have three cases where the reverse powers are the same, and the impedance match looking back toward the source is the same (1:1), yet the dissipation in the source resistor Pa(R0) is very different. The obvious conclusion is the THE POWER DISSIPATED IN THE SOURCE RESISTANCE ISN'T DETERMINED DIRECTLY BY THE SOURCE MATCH, THE SWR, OR THE REVERSE POWER. Otherwise it would be the same in all three cases, since all these quantities are the same for all three.

Not only that, but notice the last two cases. Here, the reverse power is a full 100 watts. The source match is 1:1. Yet *none* of this reverse power is dissipated in the source resistance. In fact, no power at all is dissipated in the source resistance. THE REVERSE POWER IS NOT DISSIPATED IN OR ABSORBED BY THE SOURCE RESISTANCE. The source resistor does dissipate power when the load is purely reactive, since the current

is non-zero. But you can see the dissipation bears no relationship to the amount of reverse power.

I personally don't have a compulsion to understand where this power "goes". The power is actually a function of time, and here we're only looking at the average power. We've calculated "forward" and "reverse" power from the forward and reverse travelling voltage and current waves. The "reality" of these moving waves of time varying or average power can be argued ether way. While the nature of the voltage and current waves when encountering an impedance discontinuity is well understood, we're lacking a model of what happens to this "reverse power" we've calculated. And ascribing to it the same characteristics of reflection as for voltage and current invariably lead to demonstrably wrong conclusions. ANY MODEL PRESENTED TO ACCOUNT FOR WHAT HAPPENS TO "FORWARD" AND "REVERSE" POWER AT TRANSMISSION LINE ENDS HAD BETTER GIVE RESULTS THAT AGREE WITH THE ABOVE TABLE. Othewise, it's wrong. The values in the above table can be measured and confirmed.

A final observation about this analysis is that the average power dissipated by the load resistance is the same for all three cases where the SWR is 2:1 (see note *). In fact, it will be this value for any impedance resulting in a 2:1 SWR on the cable (reflection coefficient magnitude of 1/3). The ratio of the load power when the load is matched (100 watts) and when mismatched (88.9 watts for 2:1 SWR) is termed the "mismatch loss". It has nothing to do with cable loss -- in the above example, the transmission line has no loss at all, yet the mismatch loss for 2:1 SWR is about 0.5 dB. There's no part of the circuit we can point to which is dissipating the "missing" 11.1 watts, because "mismatch loss" doesn't represent dissipation anywhere. It's simply a measure of the amount of power we could have had if we had matched the load versus what we get with a mismatched load. If we use a transmatch at the source or load, we can obtain the full 100 watts in the same load resistor from the same "transmitter", reducing the "mismatch loss" to zero. (Or we can consider the transmatch to have "mismatch gain" compensating for the "mismatch loss".) Mismatch loss is a useful concept when dealing with fixed impedance sources, but not when the impedance is adjustable. And it should never be confused with actual dissipation anywhere in the circuit, as it often is.

Some inventive people have supposed they can separate forward and reverse power with a circulator. That really sounds attractive, particularly with an open or short circuited load. In that condition, the forward and reverse powers are each 100 watts, yet the transmitter (or the transmitter voltage source) doesn't have to produce any power at all. If we could separate the forward and reverse powers and deliver them to loads, we'd have 200 watts of free power. Even just one of them would give us 100 watts to sell back to the power company. Expect to find something about this in some future April first posting. Seriously, though, if we put a circulator in the line, the source would see a perfect match, so the transmitter would produce a net average power of 100 watts, 100 forward and zero reverse. Past the circulator, there

would be 100 watts forward and 100 reverse like before (presuming an open or short circuit at the load end of the line). 100 watts would exit the circulator's "reverse" port. I'll leave it to the philosophers to argue whether that 100 watts is the 100 watts produced by the generator or the 100 watts of "reverse" power past the circulator. The fact is that 100 watts went into the line/circulator/load system, and 100 watts came out. No surprise there. But don't expect to get one microwatt more than that out of the system, no matter how clever you are.

Think about this. What happens at the input end of that 1/2 wavelength
150 ohm line when it is connected to the 50 ohm load? In other words,
what is the impedance looking into the input end of the line?

The thing about science is, you don't get to conjure up anything unless you can successfully interweave it with everything else mathematically. That's where perceptual psychology and science part company. Of course, as we've seen here, even the "math" connection is open to debate on occassion.

>Small tacks shouldn't have much effect.

Hmmm. That is surprising. What adverse thing could happen if I used
steel staples? After all, who really knows what has been hammered
into the wood framing you are running near?

I thought the only problem was coupling with a substantial conductor
running parallel to the ladderline for several feet where the distance
between was less than a couple of inches.

(1) At one spot on my wood antenna mast, I intended to hook a window
of the insulated ladderline over a light steel hook screwed into the
wood -- for support and wind stability. Is this a no-no?

(2) The ladderline will pass just under (actually just touching) a two
square foot steel (anti-squirrel) chickenwire screen over a gable
vent, perpendicular to it. Is this a no-no?

(3) Can the ladderline come close to or rest against insulated house
wiring running perpendicular to the ladderline?

Of course I can, Roy, but they don't tell me anything about TV reflections. Those equations don't answer my question about TV ghosting. Those equations only apply to continuous waves with no modulation. My question about TV ghosting is a simple one. Will there be ghosting or not when a shorted stub of an odd number of 1/4 wavelengths is attached to a TV receiver. If there is ghosting, then the stub is not providing an open circuit at the TV terminals.

And that's why I chose to switch to a signal generator equipped with a
circulator which dissipates all the reflected power in a resistor no
matter what the phase. Driving a system with such a signal generator
applies Ockham's razor, cuts through the confusion, and reveals exactly
what happens to the individual energy components.

Please perform your calculations with the above suggested signal generator
and see what your results are.

The virtual impedance is 50 ohms, Bill, but nothing magic happens
at a virtual impedance. Reflections only happen at actual impedances.
That's what all the steady-state oriented folk have forgotten and
it has turned into an Old Wives' Tale.

That`s right. I was making the simple case.

I wrote:
"There are two power pulses during an a-c voltage cycle and both of them are positive."

Roy wrote:
"Sigh. This is true only if the load is purely resistive."

Power is purely resistive by definition. Voltage drop across a resistance is in-phase with the current through the resistance, no matter what the reactance in the circuit.

I don't know anything about steel staples. That's why I didn't mention
them.

> (2) The ladderline will pass just under (actually just touching) a two
> square foot steel (anti-squirrel) chickenwire screen over a gable
> vent, perpendicular to it. Is this a no-no?

The steel screen will tend to "short-circuit" the transmission line
fields. That's why ladder-line should be kept 3+ inches away from
anything electrically or magnetically conductive. These are not DC
voltages/currents that we are dealing with.

> (3) Can the ladderline come close to or rest against insulated house
> wiring running perpendicular to the ladderline?

Insulated house wiring will distort the ladder-line's electric fields.
Again, keep ladder-line 3+ inches away from anything conductive.

In other words, if we are trying to create inductive reactance, why
doesn't that coil of coax follow the same boundary conditions as a
coil of bare wire? If we coil the two end loops on top of each
other, aren't we providing a capacitive path around the inductance?

THIS IS NOT TRUE AS STATED!

I have some explaining to do.
When I set out on this project my target was basically to improve
on what was on the market at that time, and many years have since
passed by.
The antenna I was comparing against was the conventional tribander and
loop.
Since those days a better antenna came out that has provision for
shortening or lengthening the radiators. Assuming that the moveable
element design has no losses my antenna does NOT exhibit MEASURABLE
GAIN gain, which on this thread is considered to be > 1 db.
In an hour or so (after breakfast,) I will post the programing
that I used, 'warts and all' so all can play with it. I will also post
a program where I used two elements as a beam and was able to reduce
radiator length by over 3 feet
per side.(Faulty programing ?)

Posting it for all seems to be the best way of gaining finality. So
many years have gone by, I'm getting older and more screwed up by
holding on to thoughts
that may have been explanable at the time of inception but cannot in
the present day climate.

Regards

Art Unwin KB9MZ......XG

> occurring in the region between the open circuit and the 'reverse'
> wavefront!!!!!

Bart, you and I are using different models. Your's may work but so does
mine. Here's what my reflection model says about that open circuit.

forward reflected
o--->-----> <---o--------->
I+ V+ I- V-

I+ * V+ = P+ V+/I+ = Z0 V+ = V- I- = -(I+)

I- * V- = P- V-/I- = Z0

Itot = I+ + I- = 0 Vtot = V+ + V- = 2 * V+ = 2 * V-

Vtot * Itot = 0w because there is no energy flow through the open circuit.

Everything is perfectly consistent with reflection mechanics.

> Power is purely resistive by definition.

This statement is not aimed at any particular person. It appears
that many people have forgotten the boundary conditions existing
in their models and have adopted those models as reality itself.
Every model has its limitations. When we forget those limitations,
we are positioning ourselves outside of this universe.

An instance in point: The steady-state model of a transmission
line will not handle TV reflections. If TV reflections are the
problem to be solved, a steady-state model that requires continuous
invariant unmodulated signals is not the model to choose to use.

As you look into this antenna, ignore the guru's that tell you that it will not work correctly unless fed at the lower end of one of the vertical elements like a Bob Tail curtain. No radial field required; can be mounted at whatever height you have available. I could reach up and touch the (weighted lightly) ends of mine without difficulty. Worked great for about 3 years until the trees ate it! Read Paul Carr's (N4PC) CQ September 1994 article 'A DX Antenna For 40 Meters'. Great antenna!

Source record: 136246

I have a fan antenna that I built for 20, 17, & 15 meters. The SWR is virtually flat (after much raising and lowering) The antenna does radiate. How well???? I have no idea. I have worked all states CW on 20. Last evening with nothing else on the band I worked New Zealand on 15. I have worked many other stations on 17 so I know it gets out. I just haven't figured how to measure how well it does. It's fed with coax and each antenna is seperated by about 11 inches. It's about 40 feet in the air.

CAM wrote:

>Don't your calculations depend on what's going on *inside* the
transmitter?

Provided that the transmitter somehow furnishes 100 watts of forward power, the voltages, currents, and powers beyond the transmitter don't depend on the transmitter at all. That was one of the points I tried to make in an earlier posting but obviously failed to do so. You can replace my "transmitter" with any crazy model you'd like which furnishes 100 watts of forward power, and if you do the calculations correctly you'll get the same results I did. Only the powers dissipated by the source resistor and furnished by the internal voltage source, included to illustrate some points I made, depend on what's inside the transmitter. After all, those components are, as I explained, inside the "transmitter".

> And that's why I chose to switch to a signal generator equipped with a
> circulator which dissipates all the reflected power in a resistor no
> matter what the phase. Driving a system with such a signal generator
> applies Ockham's razor, cuts through the confusion, and reveals exactly
> what happens to the individual energy components.

Adding a circulator adds a factor to simple and straightforward calculations that makes it easy to conceal and misunderstand what's going on. If you'll read carefully what I just posted, you'll see exactly how much power is supplied by the source and the "transmitter", how much is dissipated in the source and load resistors, and how much forward, reverse, and net average power is traversing the line. In other words, "exactly what happens to the individual energy components". There should be no confusion. The circulator is an obscuring factor, not a simplifying one. It certainly doesn't come anywhere near to representing a typical amateur transmitter.

>
> Please perform your calculations with the above suggested signal generator
> and see what your results are.

I've done them -- they're in the posting you just read. The results are exactly the same regardless of the transmitter, provided only that it furnishes 100 watts of forward power -- except, of course, the dissipation of the internal source resistor and the power furnished by the internal source. If you get different results with your "transmitter", then one of us has done our calculations wrong. I welcome corrections to all my postings, so please point out any errors you find in the course of this exercise.

Depends on who's doing the defining. My experience is that the term power is often used in the sense you mean, the average power, which can do work. However, power can be used to mean the rate of energy transfer. In a reactive circuit, energy is being transferred back and forth each cycle of the time-domain power waveform even if no work is being done. Therefore, there is power in each direction even though its average can be zero. A good illustration of this is in Pearson and Maler's _Introductory Circuit Analysis_. Check whatever circuits text you have on your shelf and I'm sure you'll find a similar illustration.

A short quote from Pearson and Maler, discussing the power waveform in a circuit with complex load:

"Figure 5.14 shows voltage, current, and power as a function of time. At those instants of time at which power is negative, energy is flowing to the left in Fig. 5.13."

Source record: 136257

Years ago I rented a vector impedance meter for doing a consulting job. While I had it, I wound coax into various size coils and measured their impedances. The coils were wound as I described in my posting. The impedance of such a coil is that of a broadly resonant circuit, providing a very good impedance over about three bands, and a moderately good impedance over nearly the whole HF range. I wrote up the dimensions and method, which were published in the ARRL Handbook and later picked up by the Antenna Book.

A few years ago, someone unknown to me who didn't understand how the baluns worked decided that the shunt capacitance was a bad thing. (It's actually essential to the creation of the resonant circuit which is responsible for the high impedance.) The folks at the ARRL were convinced, and the text was changed to specify a winding technique to minimize the shunt capacitance. This would raise the resonant frequency of the loop and reduce the balun's effectiveness at the design frequency by lowering the impedance. I found out about the change just a couple of months ago via this newsgroup, where I was surprised to be told that I couldn't be right about how to wind them because the Antenna Book says to do it differently! I've pointed out the problem to Dean Straw, the Antenna Book editor, and he'll have it changed back in the next edition. Hopefully the Handbook will follow suit if it's been changed.

The latest Handbook I have is 1997 and the latest Antenna Book the 17th Edition. The text in both is correct -- the change was made sometime between when they were published and now.

Shunt capacitance doesn't "provide a path around" the inductor. It interacts in an interesting way to form a parallel resonant circuit which, at resonance, has a much higher impedance than the inductor alone. Ain't electronics cool? Putting two impedances in parallel make an impedance higher than either of them!

We aren't trying to create inductive reactance, we're trying to create a high impedance. Provided that the impedance is high enough, the sign of the impedance is irrelevant.

If you somehow devise a method to measure its performance, you'll find that it's nearly identical to a conventional dipole on each band. People work plenty of DX with antennas of much lower efficiency, and some even brag about their antennas. I've worked and confirmed all states (and worked 33 countries over a few years) on 40 meters with 1.5 watts and simple antennas, and this is by no means extraordinary. People have worked much more with considerably less, and anyone with 100 watts and 1.5% efficient antenna can do the same.

Incidentally, I worked YJ8OT in New Hebrides on 40 meters with 1.5 watts to a bent dipole made of #28 hookup wire stapled to the top of the attic, 16 feet off the ground. Got a QSL card, too. And that wasn't because the antenna was great -- compared to a good outside dipole at a reasonable height, it was truly crappy.

Roy Lewallen wrote:
"The results are exactly the same regardless of the transmitter,
provided only that it furnishes 100 watts of forward power---."

It`s interesting that a transmitter with an internal voltage of 141.4
and an internal resistance of 50 matches the 50-ohm coax so that the
70.7 volts across the coax produces a forward power of 100 watts
regardless of the load at the end of the coax.

This says nothing of the power taken from the transmitter as the
reflected power subtracts from the forward power. If no power is taken
by the load, none is supplied by the transmitter to a lossless line once
the line fills with energy.

Best regards, Richard Harrison, KB5WZI

Roy,
My point exactly. I'm not a purist. I just want to talk to
people. I put up my antennas where I can. I try to get the most bang for the
buck while keeping it as simple as possible. My antennas work OK for me. The
enjoyement (frustration) I get is from the experimentation. I've been back
to active in the hobby for a little over two years now and this is the
fourth or fifth antenna that I have run with. It's about the best because I
can work multi band without a tuner. Being an avid reader of this NG I
think DOC expresses it best when he says. Just build it and see. To which
I'll add, If it doesn't work take it down and build it again.

3525. TUTORIAL #3 FINAL

Newsgroup: rec.radio.amateur.antenna
Date: 2002-08-21 17:26:56 UTC
From: aunwin@fgi.net
Message-ID: <c4becf19.0208210926.66e7be06@posting.google.com>
Source record: 136266

Continuing from the previous tutorial the antenna can be seen as
1. a loop
2. a dipole
Dealing with the loop portion first the main considerations are as
follows.
a. The loop must be oblong shaped for maximum coupling
b. Because of the mishapen loop, instead of repeating the normal 5/50
pF
capacitor it would be wise to increase the starting point capacitance
to 10/12 pF. (The choice here also determines whether it is broad
band or narrow band in nature)
c For simplicity we will place the variable capacitor on the opposite
side to the dipole, recognising that a more suitable place may be
found to decrease electrical stresses.
Now we are able to apply the loop to a program to find dia of
material used
for the given spacing or width to obtain constant impedance at a
fixed feed point for the frequency range required, which when using
capacitor values can be laborious. I chose to use a constant impedance
which gave me a common SWR
i.e.constant impedance.(adjusting later for a suitable balun)
Now one can follow the same procedure by adding the dipole to the
loop and again choose a point feed at the dipole center and run the
program again
for a common swr across the frequency spectrum under review.
Lastly we can add different points of feed using a feeding method of
your choice, either in the same plain or just hanging down as is
conventional.

The following program shows combination of above programs based on 2
inch
common members (looking at my engineering notes the idea was to weld
such an antenna for test purposes. Notes suggest dipole length of
around 200 inches ???)An unsolved mystery showing up some 6 years
later)
The computor user can go directly to one program which can readily be
seen by adding lines preceded by (;) or omit lines referring to the
dipole portion.

```
Name ' constEL '

Over ground
30 MHz
8 6061-T1 wires inches
```

```
L1 = 91.82553
x = 42.82553
K = 10.23438
y= x-K
z= 40.7748
h= 820

1 0 L1 h 0 x h 2
1 0 x h 0 y h 2
1 10 y h 0 y h 2
1 0 -y h 0 -x h 2
1 0 -x h 0 -L1 h 2
1 0 x h 6 x h 2
1 6 x h 6 -x h 2
1 6 -x h 0 -x h 2

; 1 0 x h -6 x h 2
; 1 -6 h -z 0 h 2
; 0 -x h -6 -x h 2
; -6 -x h -z 0 h 2

1 source
wire 3 ,center
impedance load
wire 7, center, 1 220

Results
impedance 122-j3
load loss 0.3%
efficiency 99.7%
Radiation peak 5.98 db @ 173 deg
So I don't lose every thing I will continue
on another postwith other sample programs.

I understand that NEC4 has the capability of using impedance

My program is AO which is quite old but still nice to have.
As an exercise use you own figures if you can for member lengths etc
```

On the contrary, Roy, it makes it virtually impossible to conceal what's going on. With a Thevenin source, people keep hopping back and forth between the wave model and the circuit model and can probably prove anything in the world.

With the signal generator, the source is always supplying a constant 100 watts into a constant 50 ohms. Any and all reflections are being dissipated by the circulator. It's a perfect example for figuring out what is really going on. If there are real reflections, the circulator load resistor gets hot. Phantom energy in phantom waves can't do that.

Power engineers use the term "Reactive Power" and assign the dimension "vars"
when the voltage and current are 90 degrees out of phase. They use the term
"Real Power" and assign the dimensions of "watts" when the voltage and
current are in phase. They don't charge customers for Var-hours. The orthogonal
sum of watts and vars is volt-amps. V * I * cos(theta) = watts,
V * I * sin(theta) = vars, V * I = volt-amps.

The sign of the power is negative by convention because the energy is
flowing to the left which, by convention, is the *negative direction*.
It's just a convention. Is money leaving your bank account negative money
or is it just traveling in the opposite direction from money arriving at
your bank account? How can one tell a negative dollar from a positive one
except by direction?

I don't know what you are talking about, Richard. If Bart has posted anything
to this newsgroup in the past week, it has not made it to my server yet.
Perhaps you could send me a copy of Bart's new posting.

Richard, you are confused about what my position is. I don't support
Walt's virtual short except as a shorthand rule of thumb. My above
statement is supportive of Steve's side of the argument. Walt has
posted why he thinks I am wrong about this. You sure seem to miss
(or fail to understand) a lot of posts.

Yes, I hadn't realized that until quite recently, and with some surprise.

> This says nothing of the power taken from the transmitter as the
> reflected power subtracts from the forward power. If no power is taken
> by the load, none is supplied by the transmitter to a lossless line once
> the line fills with energy.

Yep. In the steady state with an open, short, or purely reactive load, we have 100 watts forward and 100 watts reverse, but no real power being supplied by the transmitter. It's interesting to see how that comes about. When we first turn on the transmitter, it sees only 50 ohms, so it delivers 100 watts of net average, or "real" power to the line. When the reflected voltage and current waves arrive at the input, they combine with the outgoing waves in such a way that the voltages of the forward and reflected waves add to zero (the line input looks like an open circuit), the currents add to zero (the line input looks like a short circut), or the voltage and current are in quadrature (the line input looks like a pure reactance). The one you get depends on the line termination and length. As soon as the reflected wave arrives to cause this input condition, the line is fully "charged" and the transmitter no longer furnishes any real power, since the transmitter now sees an open circuit, short circuit, or pure reactance. The 100 watts forward and 100 watts reverse (which is a total energy of 100 watts * the round trip time) remain on the theoretical lossless line forever. Unless the impedance seen by the transmitter is an open circuit, though, the transmitter will have to continue supplying current to the line. This current will produce dissipation in any real internal series resistance, requiring the internal source to produce real power equal to this dissipation. No net average power exits the "transmitter's" terminals, though.

Disclaimer: I'm not arguing, just trying to understand why you are right
and others are wrong.

What is the resonant frequency and bandwidth of the parallel resonant circuit
you are creating? It will be inductive on one side and capacitive on the other
side. Can such a circuit have a 10/1 bandwidth or is this a narrow band
solution?

When we wind turns of coax on a toroid to create a choke, we carefully avoid
adding capacitance between the turns. Why is this any different? Can we stop
worrying about capacitance when we wind coax on toroids? Jerry Sevick
says capacitance between turns of coax on a toroid is to be avoided. Is
he wrong? Can we wind turns on a toroid until we achieve parallel resonance?

Dear Lord, no! It it doesn't work, educate yourself as to what is wrong and make it work. Give a man a fish and he will survive for another day. Teach a man to fish and he just might die of old age.

For instance, some ham sent me an email because his 20m dipole fed with 450 ohm ladder-line wouldn't work with his built-in auto-tuner even on 20m. I explained how he needed to cut his ladder-line to a multiple of 1/2WL on 20m. He did so and all the 20m problems went away. IMO, always use a non-working antenna as a learning experience.

The above ham finally chose a compromise length for his ladder-line which allowed his auto-tuner to work on 20m, 17m, and 15m giving him a three-band antenna for the price of a single band antenna.

One of my points exactly, Roy. That's why the signal generator with the circulator load for reflected power is so effective in determining what is happening. No impossible Thevenin equivalent source mucking up the works and tempting people to switch from the wave model to the circuit model in midstream.

3546. TUTORIAL final,final

Newsgroup: rec.radio.amateur.antenna
Date: 2002-08-21 19:10:34 UTC
From: aunwin@fgi.net
Message-ID: <c4becf19.0208211110.5674f6f9@posting.google.com>
Source record: 136135

From the previous tutorial we can see that the program actually did
not reflect
a 20 meter dipole. This length can be controlled by inserting for L1 a
figure close to say 200 inches and allowing other dimensions to float
for the computor to determine.

The previous program shows that even using a dipole of half the
expected 20 meter dipole, exceptable figures can still be obtained
even for an antenna that provides for HALF of the normal turning
radius.
Disregarding the said 'advantage' it brings the possibility of
doubling the frequency range by adding a switch at the dipole ends
plus an alternative switched in matching system seems compelling
The frequency range of 14/30 MHz is chosen to maintain the bi
directional feature. If one supplied a capacitor with a greater range
for use then
the bi directional feature is lost to a multi lobe formation at the
extreme frequencies but allows use of frequencies outside the chosen
range.

The following is a program for two element beam with only the driver
having
a variable capacitor

```
Name hold1
over ground
28.50 MHz
15 wires 6061-T1 wires inches

L1 = 110.1097
L2 = 100
L3 = 100
y = 38.85992
x = 54.6559
z = 2.902669
h = 820
h3 =780.0508
h2 = 820
h1 = 826.5495
a = 5.964849
s1 = 44.02934
s2 = 100.6065
s22 = s2 + a
x3 = 43.99287
x1 = 43.98962
```

```
s11 = 35.97721

1 0 L1 h 0 x h 1
1 0 x h 0 y h 1
1 0 y h 0 -y h 1
1 0 -y h 0 -x h 1
1 -x h 0 -L1 h 1

;1 0 x h 6 x h 1
; 1 6 -x h 6 -x h 1
; 1 6 -x h 0 -x h 1
1 0 y h -4 y h 1
1 -4 y h -z 0 h3 1
1 0 -y h -4 -y h 1
1 -4 -y h -z 0 h3 1
1 s1 L2 h1 s1 x1 h1 1
1 s1 x1 h1 s1 -x1 h1 1
1 s1 -x1 h1 s1 -L2 h1 1
; 1 s1 x1 h1 s11 x1 h1 1;
; 1 s11 x1 h1 s11 -x1 h1 1
;1 s11 -x1 h1 s1 -x1 h1 1
1 s2 L3 h1 s2 x3 h1 1
1 s2 x3 h1 s2 -x3 h1 1
1 s2 -x3 h1 s2 -L3 h1 1

1 source
wire 3,center
1 load
impedance load
wire7, 1 220

results
impedance 122-j3
swr 1.63
efficiency 99.7%
radiation peak 173 deg @5.99 dbd gain

I threw the above in to see effects of just loading
the driven element. For 3 element with all having a load
change to 3 loads in above. Note again the 'short'
elements , suggest user insert for L1 = 200 fixed length

; 1 s2 x3 h1 s22 x3 h1 1
; 1 s22 x3 h1 s22 -x3 h1 1
; 1 s22 -x3 h1 s2 -x3 h1 1
The above 3 lines are continuation of program.
Note. I could not find my original programs of 6 years ago but I see
no reason why the above should no be used

Best regards
Art Unwin KB9MZ.....XG
```

It's probably coupling to the 80 m antenna. To test, unhook one of the legs of the 40m antenna and swing it away at a different angle. Did the SWR make a drastic change? If not, try the other side. Once you find the side that is critical, try moving it slightly away from the offending other wire. If you can't do this, you will need to do some more wire trimming. You can get a decent match, but it will take a little tweaking. Where is the 40 antenna resonant? What is the SWR at that point? If it's resonant in within the band, but still a high SWR, you have a coupling problem. It's almost sure that the problem is the 40 legs coupling with the 80 or 160 legs. The shorter 20 legs should be having no real effect. Don't worry about the 20 antenna. I'd be looking at the relation to the 80/40 legs first. If you do have a coupling problem, and can't move the wires, slightly vary the feedpoint of the 40 antenna a few inches either way. IE: add to one side, but not the other. Varying the center point will let you match the antenna to the coax like a crude gamma match of sorts. But it's better to get the legs away from the offending other wires. If you have coupling between legs, it will effect the pattern a bit, and usually you will notice less usable bandwidth. MK

The other dipoles are interfering with the 40m dipole, mutual coupling, etc.
If you don't have one, borrow an MFJ 259B antenna analyzer and find out what
the feedpoint impedance is on 40m at resonance. If it's not resonant on 40m,
find out what is the closest frequency to 40m on which it is resonant. That
will probably indicate what you need to do.

Hm. Thought I had posted that not too long ago on this newsgroup. And thought I just said that the baluns are good over about three bands. The resonant frequency of the circuit is centered in the recommended frequency range. The bandwidth varies among the various sizes, but in all cases is sufficient to provide more than 500 ohms or so of impedance over the three recommended bands. I've only been able to locate some of the original data, but here's the impedance of one of the configurations, 10 feet of RG-58, 7 turns, recommended for 10 MHz, and also as the best compromise for the full 3.5 - 30 MHz range:

Freq MHz Z ohms

2 128
3.5 244
7 854
10 10.8k
14 848
21 351
30 198

Impedance at resonance, 9.9 MHz, is 12.7k ohms. As you can see, the impedance is adequate for standard applications from 7 - 14 MHz. It's marginal beyond that, but still provides some choking action. The other day I posted an extreme example of an unbalanced dipole, with nearly all the current in one leg of the dipole and a very heavy current on the feedline. Inserting just a 200 ohm balun at the feedpoint of this antenna restores the current on the "cold" side of the dipole to 84% of the current on the "hot" side and reduces the feedline current to 24% of the "hot" side current. Not perfect, but a great improvement over the orginal severe imbalance.

But like most designers of RF circuits, I prefer to use resistive ferrites for broadband applications, because they'll give you a high impedance over several decades. This goes for broadband transformers as well as baluns. In your spare time, tear apart a TV balun and measure the impedance of a turn or two around the core at VHF. Bet it looks like a resistor. I know for sure you'll find lots of low frequency ferrites in broadband applications in Tektronix products, and not just the portions I've designed.

If you've got something like the MFJ antenna analyzer, you should be able to make measurements similar to the ones above. See for yourself. Then get out your Coke bottles and see if you can do better. (Actually, I fairly recently came across some measurements of just that, which were posted on the web. Sorry, I don't recall the URL. As I recall they're comparable to what I got from the flat coils. He also took advantage of the coil's self resonance. So one way is as good as the other if done right.)

> When we wind turns of coax on a toroid to create a choke, we carefully avoid
> adding capacitance between the turns. Why is this any different? Can we stop
> worrying about capacitance when we wind coax on toroids? Jerry Sevick
> says capacitance between turns of coax on a toroid is to be avoided. Is
> he wrong? Can we wind turns on a toroid until we achieve parallel resonance?

Who's "we"? Depends entirely on what you're using the choke for. Chokes are used for many applications, each with its own requirements. Why do you suppose there are so many sizes, shapes, and materials that they're made from? Shunt capacitance lowers the resonant frequency of the choke. In many applications this is undesirable. In others, such as this one, it's definitely desirable. And if you're trying to make a resonant circuit, it's essential.

It's not clear to me why so many people insist that a balun's impedance has to be inductive. What's the evidence for this? All it does is force you to operate your balun well below resonance where the impedance is lower. I personally wind my baluns on low-frequency ferrite cores. Their impedance is hardly reactive at all -- it's nearly purely resistive, so they don't display any perceptive resonance. This gives me a high impedance over a very wide bandwidth, easily covering the full HF range, and VHF to boot. Shunt capacitance will lower the impedance, but not enough that I've ever had to do anything to avoid it. If you insist on having capacitive reactance only, you've got to use something like 60 series ferrite and settle for much less impedance -- or powdered iron and settle for even less. Then it becomes really tough to get enough impedance without making the thing resonant, if you insist on avoiding resonance. One note, however -- if a lot of power is involved, a resistive toroid balun can overheat even though the fractional power loss is negligible from a radiation standpoint. In that case you're stuck with having to use a more inductive, less resistive material. Or use something like the air core balun that has a large surface area and very high impedance at the point where it's resistive.

Sorry, I won't attempt to explain what Sevick says.

None of the currents, voltages, powers, or dissipations change if the transmission line length is zero. But sure as the world, some fussbudget will whine that there's nothing for the forward and reverse power to flow in. If you can live with that, you can use a zero length line.

Thanks very much for the correction. After some of the responses I've seen, I feared that no one had bothered to read what I wrote, let alone understand it. It's encouraging to know that at least one of the postings was scrutinized that carefully.

Uh oh, I hope I'm not the fussbudget when I ask what happens with a zero length line and an open circuit load. I imagine a 141 V source in series with 50 ohm and nothing else. The way I see it, I1 = 0. Your table shows both 100W forward and 100W reverse with zero dissipation either place, but I'm having a hard time visualizing these two powers. I realize your math predicts what your table shows so what am I missing?

Source record: 136150

Every solenoid, whether it is used as a tank coil, a choke, a helical antenna, or bent round to form a toroid, has self capacitance which resonates with the self inductance.

When there are more than just a few turns on a solenoid the capacitance between turns forms an insignificant fraction of the total capacitance. Why? Because the resulting end-to-end capacitance is 1/Nth of the capacitance between two adjacent turns and so is very small. The little bits are all in series. That the turn-to-turn capacitance is the only capacitance is an old wives tale repeated by people who don't think about it.

Nearly all the self capacitance of a multi-turn, close-eound solenoid is similar to that between the two halves of solid cylinder of the same dimensions as the coil. It is, of course, distributed along its length. The effective capacitance, considered as a lump across the ends of the coil, is calculable and so is the resonant frequency.

The resonant frequency of a solenoid choke or balun can easily be measured with an antenna analyser. At HF it has a very high Q. But because the impedance is very high a choke is effective over a very wide band.

Regards, Reg

Picky, picky. Ok, connect a little itty bitty line for the power to bounce around on. Then remove it. Nothing changes. The energy (200 watts * round trip time) was put onto the line when the transmitter was first turned on, then it just bounces back and forth forever without ever otherwise reacting to the outside world. Hm, better yet, fire up the transmitter, get the transmission line charged up, then disconnect it and set it on the table over by the can of beer. Now you've got your open circuit without a cable *and* 100 watts bouncing back and forth in the cable.

Seriously, without the cable there's no forward power and no reverse power. And it makes absolutely no difference at all. With or without the cable, the "transmitter" is producing no power. And you're right, I1 = 0.

A little OT for this NG but anyway...

It shouldn't really matter which distro you use.
A lot of radio amateurs use Debian. I
use Linux From Scratch or Slackware.

I forget who it was on this newsgroup who insisted that chokes should be inductive rather than resistive and thus prefers some other material over #77. It seemed to me from his posting that the choice was inductive (lower loss) Vs resistive (higher loss). Thanks for enlightening me.

> Art Unwin KB9MZ......XG

In my haste to get the previous statement on the web I forgot to
mention the following which is so important when one talks of "gain"
i.e gain over what?
In the past tutorials I likened the similarity to the simple loop
antenna.

In a standard loop case,what you have is the minimum size for 30/10 Mhz.
(And minimum gain)
There are no set conditions on the length of that part that energizes the loop
by coupling. This extreme brings certain disadvantages but the antenna is still operable.
Advantages are obtained versus more room reguired to rotate when this
coupled energizer (a dipole in my case) is lengthened to 200 inches, and there is no restriction to increasing the dipole length even more, but as always with advantages, one has to weigh accompanying disadvantages.
Though many would have seen this when looking at the models presented I felt
it was most important to bring special attention to his added variable, and is also the reason why I chose a shorter dipole versus the 200" that I suggested in earlier posts.
Best regards

Art Unwin KB9MZ.....XG

I wonder about this myself. I was reading results from this page:
http://www.k1ttt.net/technote/airbalun.html,
and it seems to indicate that winding the chokes as a coil is
preferred as far as higher frequency use. Less interwinding
capacitance, and better choking at high frequencies. Now, myself, I
have made them both ways, and both seem to work, but I never made any
comparisons. Being I used both types mainly at the design frequency, I
probably wouldn't notice any difference. I do note that the
instructions for my 20-10m A4S say to wind the choke as a coil, but I
don't know if that advice is due to actual testing. I assume they must
have done some..?? But anyway, from what I read on the above web page,
it would seem a coiled choke would be better than a bunched one. At
least on the higher frequencies used. MK

I would suspect the 20m leg(s) rather than 80m. I have an 80 / 40 vee
and they get along fine. The "general" rule (ie the way it seems to
work) is that going past two bands is asking for trouble.

And it could be the 160m antenna looking like a 3/2 wave antenna for
"53m" which is throwing the 40m legs off.

The whole concept of reflected power is a load of completely unecessary nonsense.

That's why nobody can understand what it's all about.

In any case, if anybody imagines he knows what the reflected steady-state power might be of what use is that 'vital' snippet of information ?

But no doubt someone will come in with the usual never-ending circular argument. ;o)

Regards, Reg, G4FGQ.

3570. Looking for a good 10 meter vertical

Hi, I'm looking for a good 10 meter vertical to go on the roof. I have a Solarcon AR99 up now and that works fairly well, just wondering if there is something out there that works better and how much better is it as compared to the AR99. Thanks, Jon W9JPE

The impedances reported on that page are quite similar to the ones I saw with the flat coils. What makes them better?

10 feet wound into a 7 turn coil works out to about a 5-1/2 inch diameter coil. Apparent inductance at 2 MHz is about 10.2 uH (negelcting self-capacitance)

What if we wound that 10 feet of RG-58 into a solenoid? Using a 3 inch form and close-winding, we'll have a little less than 13 turns and the inductance will be about 8.4 uH. But the self-resonant frequency will be much higher.

Neglecting self-capacitance, the impedance of an 8.4 uH solenoid will be:

2 105
3.5 185
7 370
14 740
21 1480

Has anybody actually made a solenoid like this and measured its impedance?

I did some tests on a smaller coil that I happened to have. 2 inch diameter, 2 inch winding length, about 9-1/4 turns, inductance about 3.2 uH. Dip meter says it self-resonates at 56 MHz. This little coil uses less than 5 feet of RG-58 and would only be adequate on 20 (barely) and above.

Looking at all this it becomes clear why beads and toroids are so popular ;-)

>and they get along fine. The "general" rule (ie the way it seems to
>work) is that going past two bands is asking for trouble.

My own is a three-wire 40/20/10, with each wire being suspended from the next-longer one using 5" flat-fiberglass spacers. It's an inverted V, top at 25', ends at around 12'.

I didn't have any trouble trimming it to resonance in all three bands (having an antenna analyzer handy made it a lot easier than it would have been otherwise).

The only quirk I've noticed is that the third-harmonic resonance on the 40 wire is well outside the 15-meter band - I suspect this is due to coupling with the 20-meter dipole. It's close enough that my rig's ATU can cope, though, so it's not a big deal.

Can't do a thing on 30 or 17 or 12, though - the SWR is sky-high.

|Every solenoid, whether it is used as a tank coil, a choke, a helical
|antenna, or bent round to form a toroid, has self capacitance which
|resonates with the self inductance.
|
|When there are more than just a few turns on a solenoid the capacitance
|between turns forms an insignificant fraction of the total capacitance.
|Why? Because the resulting end-to-end capacitance is 1/Nth of the
|capacitance between two adjacent turns and so is very small. The little bits
|are all in series. That the turn-to-turn capacitance is the only capacitance
|is an old wives tale repeated by people who don't think about it.

Right. Also, to paraphrase the reference below, "When there are a lot of
closely-spaced turns (where wives would guess the turn-to-turn capacitance is
high) the voltage-phase difference between adjacent turns is very small so
essentially the capacitance is shorted." (He didn't say the wives part.)

See: "Filters and an Oscillator Using a New Solenoid Model", by Randy Rhea,
Applied Microwave and Wireless, November 2000, pp. 30-42.

|
|Nearly all the self capacitance of a multi-turn, close-eound solenoid is
|similar to that between the two halves of solid cylinder of the same
|dimensions as the coil. It is, of course, distributed along its length. The
|effective capacitance, considered as a lump across the ends of the coil, is
|calculable and so is the resonant frequency.
|
|The resonant frequency of a solenoid choke or balun can easily be measured
|with an antenna analyser. At HF it has a very high Q. But because the
|impedance is very high a choke is effective over a very wide band.

May I share with you what happened years ago with my fold over Rohn
45.
It failed when being folded over. The failure occured on the upper
most corner
where the member failed under tension with all the characteristic
'necking'
before failure. I then did the necessary engineering calculations only
to find there was no safety factor designed in which leaves you very
much at the mercy
of quality factors and control on incoming steel and unconcious
stresses imposed
before and during assembly.If the design was to be used under
conditions where people are expected to be in the area such as a hoist
a safety factor of at least 3 would have to be designed in. Rohn can
design with zero safety factor since it is expected that no one will
be in the near vicinity. The fold over design was later corrected by
the addition of stress bearing plates.
Another thing to be concerned with when looking at wind tables is to
remember
that at any time a high gust of wind can occur over the maximum
specified.
Since you live in an area where storms occur how are you going to
justify
1. a gust did not occur
2. Your construction met all engineering requirements of the tower
manufacturer
so that liability can be assigned to him.
3 That structural damage did not occur when the tower was initially
blown over.
4.Everything would have been O.K. if the child had not wandered under
it.

If the tower is not going to be guyed I would at least halve the
intended height.
Think more than twice before you proceed. What do you really regard as
the most valuable to you other than the tower height. Possibly your
family will be right up there.

Power is defined as the time rate of change of the energy contained
within a closed system. Most systems have the property that energy can
either increase or decrease. Therefore power can be either positive,
negative or zero.

Point is that power is a scalar, like water is a scalar. Have
you ever seen a bucket of negative water?

He said he saw a difference between the two types of windings. I
didn't directly compare his impedances with yours. I quote:
"Whencompared to the single-layer version of the same diameter and
number
of turns, the bunched baluns show a large downward shift in parallel
self-resonance frequency and poor choking reactance at the
higherfrequencies.
"
Is this the same test, or info, from a few years ago that you didn't
agree with? MK

>
> dave, wb0taq

Dunno... I have made dozens of these antennas over the years. Not a single time have I seen a coupling problem on one band caused by a higher band element. It's always been from a lower band one. In my cases with 40m problems, it's almost always been coupling to the 80m legs. But many of those times I wasn't using 160m, so couldn't comment on that. I always start tuning from the lowest band, and go up one by one. You can have about as many bands as you want, but being as coupling is much more likely between some elements, that means you will have to tweak the wire for a better match on some bands, IE: offset the feedpoint slightly. Starting from the high band and dropping will be like a dog chasing it's tail. The tweaks you make to the lower antenna effect the higher in many cases, and it's a never ending chase. This will almost never be a problem starting low, and going up band by band.
Or move the wire to a different location and try. And you can expect the pattern to be altered some with the coupling to other legs. But the antenna will still be very efficient on all it's tuned bands. With two dipoles at right angles, there is almost zero coupling. I've had "other band" legs break, or fall down, and make no difference at all to the other band when at right angles. MK

3592. Re: Superposition quiz

Newsgroup: rec.radio.amateur.antenna
Date: 2002-08-22 06:15:15 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <3D648173.2070105@eznec.com>
Source record: 136182

From Pearson and Maler's _Introductory Circuit Analysis_:

"For our conventions the power to the right [in a simple circuit] is

p = vi = VI*cos(omega*t + phiv)*cos(omega*t + phii)"

From Van Valkenburg' _Network Analysis_:

"The rate at which energy is being absorbed is the power given by

p = dw/dt = v(t)/i(t) W (watts)

. . . For the voltage and current references shown, a positive p
indicates a flow of energy into the network, negative p out of the
network. . .

[for the steady state and a resistive load, power is]

pR = RIm^2*sin^2(omega*t) W

[and for steady state and a capacitive load, power is]

pC = (Vm*sin(omega*t))*(C*Vm*omega*cos(omega*t))"

Are these what you call a scalar?

3593. lightning protection and general grounding questions...

Newsgroup: rec.radio.amateur.antenna
Date: 2002-08-22 06:36:53 UTC
From: Andreas Hofmann <andreash23@hotmail.com>
Message-ID: <3d648682$1@news.microsoft.com>
Source record: 136183

I was reading up in the "Antenna book" and a couple of posts as well. Some of my questions remain. Here is the context:

I have a multiband dipole outside and currently just take the coax through the window, that is not going to fly in the winter season. No ground yet. I am thinking of routing the coax to the back of my ham desk on teh outside of the house, then go through the wall. This is where a grounding switch should be, so the antenna is grounded if not in use. Also, at the same point the main station ground is going to leave my shack and lead to the ground (7ft on the outside wall) where a copper water pipe will be driven into the ground.

Questions:
1. I would like to use a coax switch to ground the antenna if not in use. The MFJ 1704 has a built-in lightning surge protector. Is it safe (in terms of lightning protection) to set this switch into the ground position (and disconnect the TX side if I go away from my shack for longer periods)?

2. Is it safe to use a combined safety and station ground (HF)? Would be nice if I just had to connect all my equipment with the ground on the coax switch (which is grounded) and be done... In case of a lightning, I am worried that I damage my equipment though. How can this be handled correclty?

Thanks for you tips in advance,

Andreas, KU7T

Just guessing...

I have never worked with tubes, but something I remember to have read as usual practice is about multi winding chokes with enough distance between the windings to make them work separately and be effective at different frequency ranges. Something like:

```
___
_)
_)
_)
_)
|
|_
_)
___)
```

Could this be used for a multiband antenna? Could you coil 6 turns for the upper bands and then leave some distance (10~15") and make a second 12 turns coil on the same PVC pipe for the lower bands?

Unfortunately I do not have access any more to the HP impedance analyzer at my faculty's measurement lab, but it seems a nice way of learning to spend a couple of evenings playing with different coil forms / combinations / etc. By the way: If I managed to get access again to the analyzer, how do you measure the common mode impedance? Do you parallel the inner and outer conductors in the coax and use it as a single impedance?

Toni

My objection was that the original dimensions I had given were still present in the _Antenna Book_, but the directions for winding them had been altered. This would produce an inferior result.

The text you quote isn't comparing a balun of the "coil-of-rope" type at resonance to a solenoidal one at resonance. As you can see from the web site information and what I posted, both methods give approximately comparable results when each is done correctly.

From: Igor <maillist@rts-ukraine.com>
Message-ID: <ak2bpk$30es$1@pandora.alkar.net>
Source record: 136188

Hello All,

I am going to buy the multiband vertical AP-8A. I have an offer for reasonable price for 4 years old antenna which was not in use at all.

But I was not able to find any datasheet/description on cushcraft's web.

As far as I understood this antenna is obsolete now and R8 is a new model.

Can anybody send me an information on Ap-8A (bands, bandwidths, SWRs, maximum input power, installation requirements/restrictions, etc) as well as personal impression from this antenna.

Regards & 73,
Igor (ur5eoa)

I have for sale 1 full size "HY-Gain" beam 10 meters. fully assembled for your inspection. 13' Boom and longest element is 22' $100.00 I also have a steel tower totaling 25'. this is in 3 sections 1 10 foot st8 and 1 5foot st8 and 1 10 foot top section. I don't not have a rotator. $50.00. pickup only from Nashua,NewHampshire. I am selling these because they are to big for my new QTH. This beam has spent a large portion of its life in storage. 73's Jeff AA1GR

3600. Discone Theory Question ?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-08-22 11:20:45 UTC
From: Robert Rose <rgsrose@tiac.net>
Message-ID: <ak2hl2$60l$1@slb5.atl.mindspring.net>
Source record: 136191

Hello:

This is one of those just-wondering tyoe of questions:

My 20 year old Antenna Specialists Discone (receive only; I use for >30 MHz) has 3 radial arms,

I see that "many" of new ones on the market now, e.g., the Radio Shack version, has considerably more.

Could anyone explain the advantages, if any, of the greater number? Three usually enough?

In one of my previous Discone questions, I was advised that it makes no difference if the arms are truly grounded in the conventional manner at the antenna via a wire to a water pipe as an example, OR not.

Trying to understand a bit more on this. Is it that a "virtual" ground, or image" is set up by the arms?

I guess what I don't understand is how they can function 'exactly' the same if they are grounded, OR not grounded.

Seems like there would be "some" (small?) difference between doing so, or not doing so, even if not required.

Might someone explain the theory, a little, for me?

Much thanks,
Bob

CAM, W5DXP wrote:
"---there is no such thing as negative power."

Sure is. Ten to the minus tenth power is the same as one over ten to the plus ten.

If power is defined as the rate of doing work, wouldn`t negative power be the rate of undoing it?

Seems negative power is arbitrary. Take an automobile ammeter. Charging is marked plus. Discharging is marked minus. Were the meter marked battery, it would make sense to label the discharge rate as plus for load current delivery.

Best regards, Richard Harrison, KB5WZI

Andreas, KU7T wrote:
"---the main ground lead is going to leave my shack and lead to the ground (7 ft on the outside wall) where a copper water pipe will be driven in the ground."

Use approved clamps for connections to grounded rods and pipes. Connect the driven pipe to the structure`s electrical ground at the power meter as required by code.

Lightning exposure is via the exterior of the coax shield. Ground this at the power meter ground or as second choice at your station ground before entering the building with it.

What you with the coax after it`s grounded outside the station doesn`t make much difference to the lightning protection. If you ground coax at the electric power meter ground, it`s best to approximately share the path of electrical service to the shack to minimize difference in induced currents between electric service and coax to your radio. This minimizes voltage across the radio.

If you don`t ground the coax outside, lightning could share the impedance between the station and its ground. This could expose the station to very high potentials.

Best regards, Richard Harrison, KB5WZI

hey jon
i have used ringo rangers and other types of verticals on 10 meters and they still dont perform as well as my antron 99
if yours isnt working as well as you think it should try replacing the coax with a better grade of coax something like RG213 or 9913f
would be good
have fun

I got a nice result starting with Moorgard latex acrylic in
"Sapphireberry" ($10/qt). To a half-pint of this I added 15 drops of
lamp black universal colorant.

I prefer a brush to spraying because with a skinny antenna, you waste
around 75% of the spray paint. Moreover, no one can see the brush
marks except the birds.

I too am putting my shack together and think I learned a thing or two
along the way that might be correct and might be helpful. Much of the
published information is incomplete, inapplicable, overly general or
misleading. My conclusions:

(1) Forget about lightning protection. You don't need it unless you
need to transmit in a thunderstorm. Just disconnect your antenna. Or
you can use a switch to disconnect your antenna when not in use. The
MFJ_ will also provide surge protection against current induced by
nearby strikes if you forget. Run the switch ground to your house
ground, just like the surge protector on your PC. This will also
ground your coax sheathing, in case your other equipment does not do
this -- which it probably does.

(2) Your one-pipe RF ground is woefully inadequate. Forget about an
RF ground because with a balanced antenna you probably won't need it.
If you want an RF ground, think in terms of a field of 8 pipes in a 10
ft square strapped together with copper ribbon or heavy braid. Also,
7 ft can be problematic and you should use copper ribbon. So, try
your rig without the RF ground before you commit to a big job.

To do the job absolutely the best way -- like a commercial broadcaster
-- is a large and expensive job. Also, it is usually unnecessary.

That answers 1. I can just use the coax switch with lightning protection to ground the ant in the case I am not using the station. I do not intent to operated around thunderstorms, and here, in the Pacific Northwest, we do not have many anyway.

for 2. I am still puzzled. I know that a dipole does not need a counterpoise. I still think I should have a ground on every piece of equipment, I think this is called the safety ground. Now can I just use the case of the coax switch (which will be grounded either via copper water pipe outside or connection to house ground) as my safety ground and connect all devices? I should be able to. No?

3. A run to my house ground will be way longer than just drive a ground rod into the ground under my windows (6 - 7ft). Would be the ground rod a good compromise or DO I REALLY HAVE to connect to the house ground?

Thanks again.
Andreas

So scalars are limited to being positive, real numbers, now. My, how
physics has changed. And, since when has a bucket of water become
a scalar field? And, finally, why did Mr. Poynting use a minus sign in his
famous, and much abused theorum?

I don't know how north in the Pacific northwest you are, but in the
USA in most places all your safety grounds have to be tied together so
that there is only one ground for the building. All my equipment and
the coax sheathing are grounded to the A/C ground.

Why drive a rod in the ground to handle a surge that your A/C ground
can handle? The same considerations apply: Your dipole is a length
of wire and your house wiring is a length of wire on the same order of
magnitude. Both will have current induced in them by a nearby strike.
If the house ground works for your PC's surge protector, Why wouldn't
it work for your antenna?

If you were looking to protect against a direct hit, THEN you would
need a few ground rods and heavy braid and a fancy discharge
protector. I believe you would still have to tie the ground rods into
your house ground.

Hi Jeff,

I've had a 5BTV (80, 40, 20, 15, & 10) since I've been licensed (1980),
and it has given me no problems in the 22 years it has been up. It's mounted on
a 3 foot piece of inch & a half pipe which is driven 2 feet into the ground in
my backyard. I have no ground radials. Within the first 2 years of using it, I
accomplished WAS, WAC, and DXCC (100 countries). I think it's a great antenna
for a vertical.

Andreas, KU7T wrote:
"---Do I really have to connect to the house ground?"

It`s the law in most jurisdictions. Purpose is to minimize voltage difference between grounds. No. 6 AWG is usually specified as the minimum connecting wire size between ground rods, pipes, etc.

I have heard that a J-pole for 2 metres use is not entirely omni-directional. Is it true there is a "side" of the J-Pole that has a weeker spot to it, or a side that produces better performance? If so, can someone tell me which side is the "weaker" side?

Thank you.

CAM,
I'm sorry. I forget that sometimes folks take things quite literally. I meant that one should, indeed, try to determine what is wrong and correct it. I do that by the trial and error method. I read what I can in books and here in the NG/Internet and I go forth and apply what I have learned. We all know that what works well for one person may not for another. I build the antenna as described and hang it up. If it doesn't work I take it down and try to figure out what could be different. Maybe my soil conditions are different, Maybe it's too high (Doubt it) or too low. Maybe my radiation pattern is skewed due to proximity of the house or other antennas. It's probably the most inefficient method of doing it but it floats my boat and keeps me interested in the project at hand. Once I get it to work I generally start looking for a way to replace it :)

Hi Art,

Perhaps if you normalized your work to dBi instead of dBd, then you
would not come up with so many offbeat claims.

The impedance seems exceptionally high for a coupled antenna.
However, as AO is not a package I've used for a number of years, the
data you provide is lost on me. Perhaps you can translate some of the
more cogent details:
Ground Conductivity: ______
A wire list with x,y,z co-ordinates of each wire's two ends: ______
Size of each wire (diameter): ______
Source placement (which wire, where on wire): ______
Load placement (which wire, where on wire): ______

wrote:

>
>Could anyone explain the advantages, if any, of the greater number? Three
>usually enough?

Hi Robert,

The discone is half of a biconical, vertical dipole. Half
structurally, but still a full dipole in that there are two elements,
the disc and the cone.

The disc in some way mimics a ground plane (or ground if you will) in
that it offers an image of the missing upper conical section (the half
that is literally missing as a physical structure). Now, having
called it a ground plane may be suggestive/confusing as there is no
requirement that it be attached to a ground wire, or the shield of the
transmission line (either is an option, though rarely encountered).
It could as easily be described/called a top hat to a fat monopole
(except we are driving that hat).

Back to the first description. The biconical antenna is structured
much like two ice-cream cones tips' converging on the drivepoint.
This structure of antenna is the fundamental form for the derivation
of dipole characteristics. As such, it is a very fat dipole and a
broadband antenna for that reason. To qualify as "fat" to obtain
those widebanded properties requires that the wire skeleton offer an
equivalent surface area in place of a solid cone (which the skeleton
approximates).

The two solid cones coming together at the drivepoint offers a tapered
leaky waveguide that matches across frequencies from 3:1 to 10:1 or
more - DEPENDING on that same amount of equivalent surface area.
This, then, translates into more spokes equals more coverage (and the
corresponding less spokes...).

How many spokes are enough? Your 3 seemed to have satisfied you for
years. Adding more would offer a consistently flat response over
greater frequencies, but perhaps none that concern you. Certainly if
you add them, you will note no improvement to speak of if you are not
already suffering from SWR (there will be no increase in gain, so
nothing to mention there either).

No one argues that because we have red beans all beans are red.

In Bird Electronic Corporation`s VSWR paper is written:
"A simple algebraic subtraction (Pfwd - Prefl) yields the net power delivered to the load."

Bird wattmeters are in operation in abundance around the world even though the U.S. Government tried to prohibit their export due to the meter`s effectiveness. As you read this, someone somewhere is calculating watts using the Bird.

The Bird contains no magic. What`s true for the Bird is true for similar measurements.

You can`t succeed in arguing it doesn`t work. It does. Instead of wasting time denying the truth of Bird`s assertion, you would better spend your time learning that what you see is what you get.

What difference would less than 2.2 db make? It`s all the same if you state the reference.

We built our antennas first to 1 / 65 scale. Then we measured the performance. It`s easy at that small size. As built, full scale, they worked liked the models.

Of course, ground conditions and environment make a difference. That`s true of full-scale antennas too.

3624. Re: Hustler 6BVT vertical

Newsgroup: rec.radio.amateur.antenna
Date: 2002-08-22 18:21:21 UTC
From: IE <m9191@abc.se>
Message-ID: <us8amu8gkj1rh457kemae36tfiu4aat3f4@4ax.com>
Source record: 136215

Hi,

I have used the 6BVT for four years. First I had it mounted on ground and last two years 3 meters above with radials going out from the low point of the antenna. (Just above the roof of a building and wall mounted). Radials are going in all directions.

Compared to my beam it is a big difference (the beam is much, much better). And for 80 meter I never use it (very narrow and not good compared to my wire antennas), But I like it since it is easy to play with. On 30 and 40 I use it a lot and have worked many DX.

This fall I will add more radials to it since I have not been fair to the antenna. I have about 8 radials today in different lengths and with very weak copper wire. I think I can get much more out of this antenna with better radials and thicker wire.

The SWR is good on all bands. I have tuned the 80 meter part to 3.500 and SWR is low there as well. But SWR is one thing. I still prefer a wire dipole on 80. It is a question of S-units in difference.

I am very impressed of the possibillity for the antenna to take care of hard wind. First years I was nervous but today I trust the antenna in all WX.

This antenna is connected to the 2nd antenna connector on a TS870 so I have never used it for higher power then 70-80 W. That power it takes care of.

Earlier I have had other verticals. I can't say for sure this one works better but I feel so.

I have a computer LAN in the same building and this antenna picks up more radiation from the LAN and TV-sets than a dipole or a beam.

In conclusion I like the antenna and think it is a nice multiband vertical. I should have done the work with radials earlier. My feeling are that it worked better ground mounted, due to grounding, then 3 meters up. This antenna will stay with me for years.

3625. Modeling coax attached to an antenna in EZNEC

Newsgroup: rec.radio.amateur.antenna
Date: 2002-08-22 18:22:09 UTC
From: Douglas Stinson <douglas-stinson@attbi.com>
Message-ID: <lZ999.197894$UU1.36529@sccrnsc03>
Source record: 136216

When modeling an antenna which will be fed by a coax cable, should one include the shield of the cable as a wire? The purpose of this would be to include the effect of currents flowing down the outside of the cable.

For example, a J-pole is often modeled in EZNEC with a source bridging the two legs of the antenna. Should one also include a wire from one end of the source down to ground?

At least for some antennas modeling with and without this "extra" wire leads to vastly different radiation patterns and impedance.

Hi Richard,

It is not the 2.2 dB, it is the difference of application. Art
compares his design to designs that are not a dipole; as such dBd is
spurious.

If I add 2.2dB to his observed:
>>radiation peak 173 deg @5.99 dbd gain
for an 8.2dBi, it is still 1.5 dB below the NBS Yagi IFF both Art and
I are talking about the same criteria (and given dBd, that is
unlikely).

When I modeled the j-pole in EZNEC I found a SLIGHT asymmetry, with the lightly less radiation in the direction of the stub, presumably because the currents are almost but not exactly equal in both legs. From a practical standpoint, the difference seems negligible. I've heard people report larger differences with real antennas, but I've often wondered if this had more to due with the feedline than anything else.

Art listed some specifications some time ago. I wrote then that his list needed refinement. Here are some items his list might cover, not in any particular order, or complete, or without surplus. It`s just a start:

1. Frequency
2. Gain
3. Polarization
4. Pattern
5. Bandwidth
6. Impedance
7. Power handling
8. Steering
9. Construction
10. Environment
11. Efficiency
12. Size
13. Cost
14. Ease
15. Probability of success

Someone can add or subtract from this list and prioritize the items according to the application.

Best regards, Richard Harrison, KB5WZI

Bingo. Yes, you should include the wire representing the outside of the coax, and yes, you'll see that the J-Pole pattern is affected. (You'll also find that ground plane antennas are subject to the same problem.)

The problem is that to be truly accurate, you'll have to model the actual path to ground. That would be from the antenna to the rig, then however the RF gets to ground from there. This is often impossible, but some experimenting with the model will at least show you the general magnitude of effects you could have.

To add a "current balun" to the system, insert a "load" in the shield wire. Its impedance should be the impedance of the balun. If you don't know what the balun's impedance is, use 500 ohms or so as a ballpark estimate. It won't matter if it's R, X, or a combination. You'll find that for a J-Pole or ground plane, you might need two baluns, one at the feedpoint and one about a quarter wavelength below.

I am the curator of a museum here for products that combined viable ideas with less than stellar results. For example we have the first container of Chicken Ice Cream (Patent Pending). The creator noted that fried chicken and Ice Cream were both great sellers and was sure combining the two would make him a fortune.

Would you be interested in donating your famous (Patent Pending, (c), (R) fractal amateur antenna? Unfortunately we have not yet received 501.C3 status and your donation would not be tax deductible. It will be mounted with a plaque with your name "Donated by Dr. Nathan Chip N1IR Fractenna Phil Et. All Cohen Ph.D." and will be displayed with copies of your e-mails relating to fractal antennas. The e-mails exhibit will be delayed as we have less than 200,000 Square feet.

Please advise us of your decision as soon as possible as we are also considering a motor driven pogo stick.

TNX, Roy - but that's for baluns using RG-213. W3RV is looking for compact and light - RG-58 size. (RG-8X would be nice but it's foam and not the best stuff for coiling). Maybe somebody with an analyzer and some '58/U can make a few tests...

Looking at the K1TTT info, it seems to me that the 'solenoid' (single layer) design has some advantages over the 'pancake' (bunched) design. For the same amount of coax, 'pancake' design does give more impedance at a lower frequency. But it does so at the expense of bandwidth.

Consider the two '8 turn 6-5/8 inch' sets of numbers. The solenoid design gives an impedance greater than 500 ohms from 6 MHz to 24 MHz - a 4:1 frequency ratio that covers 40, 30, 20, 17 and 15 meters. The same coax in a pancake design gives an impedance greater than 500 ohms from 4 to 10 MHz - only a 2.5:1 frequency ratio.

Once again:

What the Bird manual fails to mention is that when the load is
mismatched, the indicated values of forward and reflected power are both
wrong, because the meter is not being operated into the load impedance
for which it was calibrated.

But by subtracting these two wrong readings, you get the *correct* value
for the net power delivered to the load!

This is quite a surprising result, and the reason is far less obvious
than you seem to think. It's explained in 'Reflections I' at the end of
Chapter 3.

Check out the Imax 2000. A very nice antenna that out performs the
A-99 due to it being a 5/8 wave. The A-99 is only a 1/2 wave and the
Imax doesn't require a ground plane. You may need to trim it a little
or use a tuner to get it right on for 10m, but outta the box, it
should perform fairly well.

Tom, KA6RUH wrote:
"I`m sure they (Bird wattmeters) do just exactly what the manufacturer represents them to do."

Good. So am I. Bird wrote:
"A simple algebraic subtraction (P forward - P reflected) yields the power delivered to the load.

That`s a description of forward power and reflected power in the 50-ohm coax, which the wattmeter indicates. It is not specific to the Bird wattmeter. With a dfifferent directional coupler you could calaulate the difference of indicated forward and reflected powers and make the same measurement, the same way you make it with the Bird.

Were the forward and reverse powers not simple scalar powers, the Bird wattmeter would not work the way it does. The fact that Zo is nearly resistive forces the current in a single direction on the transmission line to be in-phase with the voltage which causes the current to flow.

Best regards, Richard Harrison, KB5WZI

Was the operation successful? Were there any new HF frequencies produced? Was it Ceasarian?

Used for a year, sounds like all fractal magnetics electrons were all used up, any gain left?

How good is the shape?

Inquiring minds or never minds wants to now.

I am sure Walt Maxwell got it right in "Reflections".

When errors cancel to give the "correct" result, I say HOORAY!

Bird only included a warning about affecting the line length at VHF by inserting the wattmeter when the line had a high VSWR. That can give a significant error. They suggest making the wattmeter a part of a 1/2-wave line. Something I had all our technicians do long before Bird published the suggestion. They may have got the idea from me for all I know.

Bird has no need to warn when two wrongs make a right.

Best regards, Richard Harrison, KB5WZI

I had the 4BTV for many years. I assume it is basically the same as the 6BTV other than a few more bands.

Actually I had the 5BTV. It had the KW 80m resonator.

I agree...it is not good on 80m anywhere. Its too short you know.

On 40 I found it worked out quite well. In Germany, when I was DA2LJ, I used the 4BTV sticking out of the top floor attic window in the roof. Ran one radial per band. Worked gangbusters. Of course it was 110 feet in the air at that time...hi.

Back stateside I used it in my backyard by putting it on a 10 foot pole. Then running a screen of interconnected chicken wire as a above ground counterpoise. Seemed to do quite well that way too.

The worst situation I used it in was ground mounting with no radials.

Hope that helps.

Hi Gene,
I'm learning, I'm learning. He just "proved" that, because his
Bird
works the way the manufacturer says it does, that the power flow in an
electromagnetic wave in a transmission line has magnitude, but not direction.
That's a new one on me, and as soon as I finish typing this, I'm going to send
a nasty note to a certain electromagnetics theorist telling him that he is
wrong,
and the reason I know he is is because of Richard Harrison's Bird. There ought

to be a law against all these dang academic theorists with their lying ways
telling
gullible hams, like me, untruths, fabrications, and real stretchers.

Thats fairly normal I think. I notice that quite a bit. I just stick a small tuner inline if I'm going to work 15. Rigs are more picky on the SWR these days, so anything over 2:1 starts getting notice. Back in the older days with the tube rigs, it was not critical at all, and most didn't worry about it as long as the loading was within range. I know I didn't even use an SWR meter at all when I first started out. I just tried to load the rig. If it loaded within range, good enough. My old valiant I once had would load a very wide range. I can run my old drake T4XB or my TS-830 at 3:1 SWR all day if the loading is in range. Not quite that easy these days with the picky solid state finals. MK

As I am sure you know, by not having the Bird meter be part of a 1/2 wavelength line in a high
swr feed line does not cause a meter reading error by itself. But changing the length of feed line
by inserting the meter and it not being a part of an additional half wavelength line, detunes the
transmitter. That changes the power out and thus the error.

As was stated before the Bird meter does not measure forward and reflected power directly.
You can easily prove it with an open circuit (no load) connected to the meter. The meter will
read the same forward reading as reflected reading. Turn the transmitter up so the meter reads
100 watts.
100 watts forward minus 100 watts reflected is zero power delivered to the load. But there is
no 100 watts reflected as the meter shows. There can be significant errors in reflected power
readings as swr goes up.

Regards
Gary K4FMX

What some consider a waste of bandwidth, others view as entertainment.

Sure beats the heck out of the 1 + 1 = 4 debates. You now know the thread title, ignore it as you go by.

Why is it you have this burning need to play bandwidth cop? Get a hobby.

Hi Ron!

Thanks for the input. I'm trying to get an idea on what direction I
want to take on putting an antenna up. Nothing fancy, just something
to get me back on the air.

Hi!

Thanks for the input. Sounds like the vertical is working pretty
well.

I'm debating between this and the DX-77 because I want a tilt over. I
know the 6BVT isn't a tilt over but that doesn't mean I can improvise.
:)

Again, thanks for the input and I'll have more to digest.

Hi Dan,

Thanks for the info. So the ground mount gave you problems. Hmmmm,
kinda strange since others I've talked with said it worked best ground
mounted but a real burden when elevated. Maybe ground conditions are
a big factor as well.

I'm debating between this and the DX-77 because of the tilt over. I
know the 6BTV ins't a tilt over but I can always rig that up if I need
to. More info to ponder. Thanks again, Dan!

Gary, K4FMX wrote:
"As was stated before the Bird does not measure forward and reflected power directly."

A speedometer measures neither miles nor hours. It never the less indicates MPH.

All measurement devices have limited range and even more limited accuracy.

Bird suggests limiting reflected power to 10% of forward power for accuracy.

Process instruments have zero and span adjustments for calibration over a limited range. It`s unreasonable and fruitless to expect more.

Best regards, Richard Harrison, KB5WZI

Sorry for the misspelling in the message. It might gave some missunderstandings. Just to be sure: My impression is that it worked better placed directly on ground.

I mounted it higher since I liked to have it up from pets and children.

My grounding is mostly sand based so it is not the best for a vertical. Still this one seems to work better directly on the ground. When I had it placed so I had no radials but a 2 meter metal tube right down as grounding.

Today I have, beside the radials, a 4 meter copper pipe down in the sand as well,

Good luck with your choise.

|When errors cancel to give the "correct" result, I say HOORAY!

The $200,000 HP8510C that I used to use had lots of "errors" too. Source match less than perfect, coupler directivity and coupling factors less than perfect, receiver tracking less than perfect, etc...

But by measuring known standards and thus determining these errors, they could be subtracted from the measured data to give the "correct" result. I always said Hooray too and wasn't troubled at all knowing that my equipment wasn't perfect.

The corrected answers seemed good enough to me.

Hi!

Ok on the followup. That clears things up a bit. Like I say, it
appears that others are having good results ground mounted and
without radials then adding radials later for the lower bands.

The ground here is dry and sandy. Las Vegas, NV, what would you
expect? :) At least this gives me some idea on the direction I want
to take.

But before that, "one wrong makes a wrong"! Certainly it has led you into some naive assumptions about how your Bird works.

Doesn't it trouble you that with any mismatched load, the forward and reflected "power" readings are both WRONG? Isn't it just a little bit curious that the difference between those two wrong readings comes out correct?

Doesn't it suggest that the whole thing is deeper than you thought? ... and certainly deeper than the Bird manual reveals.

That does not mean that either flow of power is negative. That is
simply a matter of convention - so that we can indicate the direction
of flow relative to some reference.

If there were such a thing as negative power, then I would expect that
it could be generated and stored. Such a power source, if hooked up to
a resistor, would cool it.

3670. Re: Air-Wound Balun Design Info??

Newsgroup: rec.radio.amateur.antenna
Date: 2002-08-23 08:35:30 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <3D65F3D2.3070609@eznec.com>
Source record: 136110

Unfortunately I don't have my data from the original measurements using RG-213. (My measurements were done in 1985.) I do, however, have some graphs of RG-58 flat coils of two lengths and various numbers of turns. Of these, the best had just over a 3:1 frequency range at the 500 ohm points. I see from K1TTT's data that he was able to achieve 4:1 with one configuration and nearly that with another. The other two, though, were less than 3:1. So I'm not entirely convinced that the flat coil is inherently more narrow than the solenoid if wound with the same type of coax and carefully optimized. It might be -- if so, I'd estimate a ratio of about 3:4, flat:solenoid for bandwidth.

I do like the flat approach because it's fast, simple, and low weight and bulk. But there certainly is more than one way to make an effective air core balun. And if maximum bandwidth is the goal, other methods might well be better.

Whatever method is chosen, though, I believe you'll find that the maximum bandwidth will be achieved if you make use of self resonance, and don't try to restrict yourself to the region where the device is inductive or to prevent resonance.

Neither one is correct. There is a problem with the ")" right after
the first Xi^2 term. There is at least one other bracketing problem as well
in the first equation.

Uh!??????????

Pardon me, but how can a Fractal (or Meander) antenna POSSIBLY be in good shape? It's a bit like the famous British politician who said "... and Britain is not an island, you know!", or "for sale, parakeets, on higher perches".

B.R. from Anony Mouse (Harry Lippitz, really, but I don't want to publish my name.)

> readings as swr goes up.

That's easily understood. Add 1/2WL of open circuited lossless 50 ohm coax and you will have the same reflections as the open-circuited Bird is reading. The Bird assumes it is in a 50 ohm environment. According to reflection mechanics, the forward and reflected phasors at an open circuit look like:

```
forward reflected
o--->------> <---o---------->
I+ V+ I- V-
```

The sampled current in the Bird equals zero. The sampled voltage equals 2V. Just as it would if it were looking into a 1/2WL open circuited feedline.

Tom, would you take some isolated negative RF power and show me how to generate
a negative RF field strength with it. I've got this idea for a broadcast station.
It seems to me the FCC doesn't require a license for a broadcast station that
is putting out a negative field strength and radio receivers should be able
to receive its signal just fine.

Yeah well Nick, let's face it, during Desert Storm the Iraquis couldn't kill any of our guys, so they got a trigger-happy Yank to do it for them. Of course it wasn't the trigger happy Yank's (yet to apologise or be held accountable) fault, but likewise the Swiss cable-car downed by the show-off doing aerobatics, and many others in between. Even the "friendly" Afghans have to start running when they see the Yanks coming.

Let's face it, if you are not yourself American then you are a legitimate target, wether you be ally or enemy. But since the casualties of this US foreign policy are not themselves Americans, I don't suppose it matters much to your average US citizen.

3681. Losses in insulating materials

Newsgroup: rec.radio.amateur.antenna
Date: 2002-08-23 12:52:24 UTC
From: Jean Cesario <jean.cesario1@libertysurf.fr>
Message-ID: <3D663008.163B82D1@libertysurf.fr>
Source record: 136022

Hi everybody

I'm wondering about losses in antennas made of standard "domestic" stranded or solid copper wire, insulated with polyvinyl chloride. I built several decametric antennas, from simple dipoles to a cubical quad, with these kinds of wires, 1.5 or 2.5 square millimeters. The results where satisfying. They probably would be better with naked wire, but how much, and how long ? It seems to me important to avoid surface corrosion and consecutive HF resistance increase and mechanical strenght decrease.

I never found practical informations about this matter. Can anybody help ?

73 de Jean F8BXG

3682. What am I emitting on 80M?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-08-23 13:03:18 UTC
From: cprstn54zz@att.net
Message-ID: <3d663141.262268750@news-server.optonline.net>
Source record: 136023

I am putting 100 watts at 80M into a shortened inverted-V dipole with center 40 ft up. The only contacts I have been able to make are after dark to a densely populated area 20-30 miles to the west, behind a nearby hill that blocks line-of-sight to the contacts.

Is my signal going straight up and these folks are seeing scatter off my pillar of RF? Will scatter travel that far?

3683. AM DXing: Why I know so little that.....

Newsgroup: rec.radio.amateur.antenna
Date: 2002-08-23 13:21:04 UTC
From: FACE <AFaceInTheCrowd@today.net>
Message-ID: <1cccmuc8onj2dd68t94l2ngh24ebtt5q8c@4ax.com>
Source record: 136025

I come hat in hand with some specs and ask if they are reasonable for
an AM DXer radio.

These are from the AM specs section of a Yamaha cr1020 receiver, circa
1977:

AM SECTION
tuning range: 525 to 1605 khz
Sensitivity (IHF, bar antenna) : 300 ï¿½V/m 49 dB/m
Selectivity (1,000 khz): 30 dB
Signal to noise Ratio: 50 dB (at 80 dB/m)
Image rejection (1000 kHz): 55 dB
IF rejection (1000 kHz): 40 dB
Spurious Rejection (1000 kHz): 55 dB
Total Harmonic Distortion: 0.4 % (for 80 dB/m)
AM Tuner Output Level Impedance(30% mod at Rec Out): 120 mV/6.5 kQ

Now, I understand the tuning range and some of the terms but not the
quantifications.....and that's it. :-)
Do you people see anything particularly bad or good there?

The receiver has a 10 inch analog tuning dial and needle dialed meters
for signal strength and tuning.

Also, the unit has a 6" ferrite bar swing-out antenna on the back
which I will try to increase the sensitivity of with a long
wire(suggestions appreciated on that last). It has a single pole AM
antenna input terminal and ground terminal.

I am 2/3 towards the edge of one of the largest metropolises in the US
which has been called the 'the most wired' city so I will have
competition getting propagated waves (I think).

My goal is to get most of the clear-channel AM BCB(Broadcast Band?)
stations on the Eastern seaboard. Is this realistic?

Thank you,

FACE

3686. Connector Question ?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-08-23 13:37:41 UTC
From: Robert Rose <rgsrose@tiac.net>
Message-ID: <ak5e1p$6mt$1@slb5.atl.mindspring.net>
Source record: 136027

Hi,

Installing a new discone (receive only) in attic.

The connector on the antenna is one of those 239 varieties which, as I understand it, is generally
used for <30 MHz.

As I will be hopefully trying to pull stations in up to about 1.5 GHz, I'm wondering if
I should try to midify it to an "N" ? Or, will the loss thru it (up to the 1.5 GHz) be so minimal as to be essentially meaningless?

The ends of my coax to my receiver, and my receivers input are presently "N's"
My coax is the large diameter (0.4 inch) CQ 106 / LMR 400 type.

Thanks,
Bob

> Do you people see anything particularly bad or good there?

I'm going to skip the specs part and move on to actual reception. Tuners/receivers from the 70s take a pretty bad rap across the board for being deaf on AM and that opinion is somewhat justified. I have a Sansui 8080db and for a couple of years I figured it was 'normal'. But, I gave it a good alignment - yes, it was WAAAAY out of whack - and it turned into a tolerable AM receiver.

> Also, the unit has a 6" ferrite bar swing-out antenna on the back

An external random-length wire, as long and as high as you can get it, will outperform the ferrite bar many times over. The downside of this is overload by local broadcast stations. You mention living in Metropolis so that could indeed be a limiting factor. There's no specs listed to quantify this...they only tell ya the good things. Overload on BCB is a problem in almost all consumer-grade solid-state gear from the 70s when you want to use a good antenna. Its still worth a try. Leave it disconnected when not in use to avoid static build up or surge problems from nearby storms. Don't depend on gadgets to totally protect your receiver's front-end in this regard.
>

If you're in LA, no. If you're in Baltimore, sure. Of course nighttime only with some degree of fading.

Good luck,
Bill

"I am putting 100 watts at 80M into a shortened inverted-V dipole with the center 40 ft up. The only contacts I have been able to make are after dark to a densely populated area 20-30 miles to the west of a hill that blocks line-of-sight to the contacts.

Is my signal going straight up and these folks are seeing scatter off my pillar of RF? Will scatter travel that far?"

My response will be as if these were genuine questions.

Your direct path is blocked but nighttime radio contacts are possible. This is normal at 80 meters. Surface attenuation of signals is high.

No ionospheric propagation during daytime hours. At night the ionosphere changes to an effective reflecting layer with relatively low loss so you can make the 30-mile trip with nearly vertical incidence signals. The "skip distance" is very short.

Scatter is good for much greater distances than 30 miles. But, loss is very high and requires high ERP. Scatter would work during daylight hours. Yours doesn`t.

Best regards, Richard Harrison, KB5WZI

|
|Neither one is correct. There is a problem with the ")" right after
|the first Xi^2 term. There is at least one other bracketing problem as well
|in the first equation.

Okay, how about:

(Vrms^2/(4*Ro))*(((Ri-Ro)^2 + Xi^2)/((Ri+Ro)^2 + Xi^2))

I think that's why they invented Mathcad <g>

If you're talking about the E field, it's a vector. If you're talking about
the H field,
it's also a vector. If you combine them according to Poynting to find the
direction
of energy flow, that's also a vector. If a vector is pointed one way it's
positive, if
turned 180 degrees, negative. There's a device that deals with negative field
strength, it's called a receiving antenna. If you don't care which direction
your
watts are going you can signify the fact by taking the magnitude only, but the
power
from your transmitter will still have a magnitude and a direction.
73,
Tom Donaly, KA6RUH

(P.S. E X H is a vector. If it had been E dot H it would have been just
another
number without direction in space, a scalar.)

> around 200 inches ???)An unsolved mystery showing up some 6 years
> later)

How time flies. I have now retrieved an ealier notebook which solves
and adds closure for me to the above.

The welded antenna WAS 200 inches in length, the weld being made to
provide for good connections with the loop efficiency in mind and with
no changes of member diameters that can affect later efforts of
computor programing
.The robustness of this 2 inch aluminum tubing was also to provide for
an EXTENSION of the coupling length which INCLUDED the original
loop,and also used the same capacitor which in this case I used one
that had the maximum range possible.
Thus I had two loops with a common capacitor to examine the
effects on radiation BEYOND that implied by use of the smaller loop
alone. I might also add that I use fishing poles as support members
for wire sizez that I may choose I.E.the wire lays on the inside of
the pole.(Adjustment must be made for the dielectric in the normal
case but with this antenna wire length is not a factor.
A rather unique feature if I may say myself, which removes the 'cut
and try'
burden that all hams must carry.)This makes things so much easier for
the experimentor and now allows be to get rid of the large stockpile
of aluminum that I have procured over many years.

But so much fun! Is bandwidth still a problem?
It was with an 8 meg 286, a 1200 baud modem,
4 megs Ram, and a 10 meg harddrive -- but
nowadays? Smile. Let's have a little fun --
perhaps with a gas fired pogo type self
elevating tower!

Source record: 136037

Doug, you have hit on what is possibly the central weakness of most antenna modeling programs available today. None of them address the issue of feeding the antenna.

Take for example the NEC core. It places a voltage on, or inserts a current at, the sub-section adjacent to the feed-point. It doesn't care how you feed it. One could model a gamma/tee match but you just move the problem to feeding the match.

Much of the early work, which is when accurate measurements were made, was done on monopoles over a semi-infinite ground-plane. The measurements and theory agree reasonably well. In fact, as modeling has become better the agreement has got better - which speaks well of/for the measurements. With this assurance, antenna modelers then appeal to 'image-theory' to say that a dipole is a the combination of a monopole and a perfect reflection of itself. Not bad, but we have a good model for feeding a monopole that doesn't transfer well to a dipole. The hole in the infinite plane through which the monopole emerges can be modeled well. It is often referred to as a "magnetic frill". No-one has ever demonstrated a dipole excited by a magnetic frill!

So your question is on the cutting edge of the state-of-the-art in this area. I will be interested to read other comments.

The CR1020, in it's day, and even today, was a very nice
receiver. I have the CR1000 -- still running, but it is
FM only. The CR1020 was not designed for AM DXing.
It was intended for good clear reception of a good local
signal with a minimum of distortion -- not a distant
signal. Sorry -- nice receiver for HI FI application,
but lousy for DX!

Don't know how the power company does it, but in the 60's on the Nike Herc site where they had installed new HIPAR radar with three 250KW gensets we used to syncphase them to bring a second genset online. The control panel had a light that flashed at varying speed depending on how far apart the gensets phases were. The slower the light flash, the closer together the phasing. Adjustment of the engine speed of the oncoming genset brought the phases together. When the light got so slow it went out, you hit the ON button and brought the second genset online. If you missed, you got a big BANG and tripped breakers.
We also phased them to the commercial power line the same way to change to genset power alone.

Unless you have a VERY GOOD GROUND under the vertical most of the radiation
will just heat the near vicinity soil.

Good ground meaning bunches of radials. Many studies have been made on this
subject over the years,

A good compromise is a counterpoise above ground system, which is what I
described to you earlier.

The 4/6BTV is basically a 1/4 wave electrical radiator. Don't confuse this
with, say, the GAP which is a center fed vertical dipole for all practical
purposes. Which btw, is a much better design than ANY 1/4 waver.

Not a problem. Corrosion on the surface of an antenna is cosmetic
(will not affect performance). Corrosion on antenna contacts is
another and more serious matter. Dry, clean, and tighten connections;
and then seal them from water. [contacts also include where elements
- like tubing - are joined together]

I am still studying for my next one.

80M and 160M dipoles are usually mounted too low, resulting in a
propagation pattern known as NVIS, which means your signal is more or
less going straight up. Nevertheless, an appreciable amount of it
does more than warm up clouds, especially in winter. With an amp, you
probably have a decent enough rig that is cost effective for casual
(non-contesting) use.

The alternative -- a homongous vertical or dipole 250 ft up -- is not
only expensive but impossible for most of us. There are folks here
who have a couple of acres filled with over $30,000 worth of serious
antenna hardware who must find we antenna-challenged hams mildly
amusing.

I believe Richard KB5WZI is correct -- that my signal is reflecting
off the ionosphere even though it is hitting the layer almost at 90
degrees -- just like light off a mirror.

However, he does not explain why no one beyond 30 miles seems to hear
me. If I am bouncing strongly off the ionosphere to 30 miles behind my
hill, I should be good to around 800 miles.

Ken,

What you have there is a cloudwarmer. You are mostly correct
in your conclusion that most of your signals are going
straight up.

During the day, the absorption of the D layer ensures that
your range will be very short. After the sun goes down
the absorption will lessen and you will be able to make longer
distance contacts. The term for local non-skywave contacts
on HF is groundwave. Groundwave contacts work best
with a vertically polarized antenna. Skywave propagation
will improve with the change of seasons. D-layer absorption
is at its highest during the summer months simply because
the sun is up longer!

The terms "scatter" and "line of sight" refer primarily to
VFH/UHF signals. We are talking HF here, got to keep
those terms straight...

Then there is the nature of the inhabitants of the 75/80 meter
bands. Some of the old curmudgeons there have not made
a non-net non-scheduled contact in YEARS! In fact, many
years ago I was told by one of those old crustaceans that
"We don't call CQ on 75 meters." Oh, yeah!?!

Just ignore that and carry on.

Come to think of it, most of those old crabs seem to inhabit
these usenet groups too... Ignore them also!

You might be putting 100 watts into your feedline, but perhaps not into your antenna. Depending on how much the antenna is shortened and how acute the angle of the V is, it can provide a severe mismatch to the feedline. Ladder line can tolerate this without much loss, provided it's dry. But if you're using coax, especially a long run of coax, the loss might be quite substantial, and you'd be better off going to ladder line and/or lengthening the antenna.

Some tuners also will be pretty lossy when faced with an extreme impedance, and this might be part of the problem.

As other people have pointed out, it won't be a great antenna, but you should be able to make contacts at much greater distances than that at night.

> feeding the antenna.

The reason is that, except in the case of phased array antennas, the feed system has nothing to do with the antenna's gain or pattern, and these are the primary things antenna programs are intended to calculate. The calculated antenna feedpoint impedance can be transformed to a value of your choice without any impact on the antenna performance at all, except for whatever loss the transforming network has.

> Take for example the NEC core. It places a voltage on, or inserts a
> current at, the sub-section adjacent to the feed-point. It doesn't care

> problem to feeding the match.

NEC doesn't directly allow current sources, only voltage. However, when a single source is used, it makes absolutely no difference to the results what kind of source is used. As you say, you can model something like a gamma match with NEC-2 or derivatives. If you're interested in impedance matching networks using lumped elements, which NEC-2 doesn't allow directly, there are programs which can do this, such as MicroSmith (no longer available) and WinSMITH. The impedance match only affects the impedance seen by the transmitter, however. It has no affect on the antenna. Again, the exception is phased array antennas, where modeling programs can give you essential information about feedpoint impedance needed to design a feed system, but can't include anything but an all-transmission line feed system in the model.

> magnetic frill!

None of the commonly used antenna modeling programs use the approach you describe when modeling antennas over ground. MININEC does use an image approach when calculating the impedance and currents by assuming a perfect ground during those calculations. This is a good approximation

provided that the antenna doesn't contain any significantly radiating horizontal wires lower than about 0.2 wavelength. But it does take ground conductivity and permittivity into account when calculating the radiation pattern, which is not the simple image approach you describe. NEC-2's Sommerfeld ground (called High Accuracy in EZNEC) does a true field calculation using finite ground parameters even for the impedance and voltage calculations, and uses a similar approach to MININEC for determining the radiation pattern.

Ken,
Assuming that you have a reasonable match to the antenna, and that the antenna is somewhere close to resonance, you're probably 'emitting' 100 watts, or close to it. With the antenna apex at 40 feet, I would think that the majority of the signal is being radiated at a fairly high angle, in a mostly omnidirectional pattern. It depends on how your antenna is shortened, and how much it is shortened. But even so, you should be heard in other places (not going to be a 'window breaking' signal, but someone should hear you).

Tdonaly wrote:
"If you`re talking about the E field, it`s a vector. If you`re talking about the H field, it`s also a vector."

As Gabriel Heatter used to say on the radio: "There`s good news tonight!"

The ham doesn`t have to do vector analysis, know a cross product from a dot product, or divergence and curl from hair problems.

The minus applied to power on a transmission line indicates its direction of travel. This negative power is not absorbing energy. It is used to determine net power flowing through the line.

On radio frequency lines, the characteristic impedance is an almost pure resistance. This means the voltage and current are in-phase for the waves traveling toward the load and away from the load. SWR is just a manifestation of the two waves passing each other in opposite directions.

SWR has a 90-degree displacement between voltage and current because the reflected wave has a phase between its voltage and current of 180-degrees. This out-of phase condition of the reflected wave is due to reflection mechanics.

The incident current and voltage waves are forced to travel down a transmission line in-phase by Zo, a resistance for practical purposes.

A mismatch in the line reflects some or all of the incident waves. Interference between the incident and reflected waves produces the SWR.

Note that the distance between an SWR voltage maximum and an SWR current maximum is always 90-degrees. This tells us that the difference in phase between voltage and current in the reflected wave is 180-degrees. The relative velocity of waves traveling in opposite directions produces the 90-degree phase in the SWR.

If vectors are all in the same or opposite directions, we combine them algebraically. They add and subtract just like buckets of water! We don`t even need trigonometry to work such a problem.

Best regards, Richard Harrison, KB5WZI

Keep studying.

Too low is a relative thing. For DXing, higher would be better, but for shorter distances, lower might be better.

Nevertheless, while I am a real casual DXer and mostly work 20 meters (300+ worked), I have 75 countries on 75-80 (including, JT, XZ, XT, BA, TI9) using an "inverted-vee" with the apex at about 40 feet.

During the winter months I've had ragchewing roundtables with lots of Europeans and have a lot of them calling me. This is from the depths of Southern Arizona, not exactly a great DX location.

I anticipate getting the other 25 needed for 80m DXCC (and thus 5BDXCC) this winter using this same antenna.

Now all of this is anecdotal and doesn't mean a thing about the merits of antennas, except that with perseverance and a modicum of skill you can overcome significant antenna limitations.

"---why no one beyond 30 miles seems to hear me."

Low antennas have high angles of radiation in the vertical plane, especially those with substantial horizontal polarization.

A good ground system and conversion of your inverted-V into a vertical antenna might do a lot for your low angle radiation. The inverted-V will do well over a good ground, or maybe a not so good ground, if you get it up in the air. It`s too low now to expect DX.

Hi Brian,

Lossy is in the eye of the beholder. Let's simply offer a worst case scenario (or is it really?) where a single bead looks like 5 Ohms with 50V RF across it (the current of which it is thus trying to snub). Well, by all methods of adding power, it looks like this bead will flame out after trying to shed 500W heat. Quite lossy.

Clearly, 5 Ohms reactance would be quite frosty.

Well, let's put a little more engineering into this. 5 Ohms is clearly not the best choice when 20 Ohms is easily found. And where one failed, how would 10 beads fare? With the same 50V RF across it we now find the assembled beads trying to shed 12.5W heat. The beads will run very hot to the touch. Quite lossy.

Can your air choke present better than 200 Ohms reactance? Presumably that and more - Still frosty.

Now, which scenario is "more" lossy? Could "more" lossy mean more efficient at snubbing current?

Further consider that I run with at least 40 beads each exhibiting at least 25 Ohms resistance (almost no reactance). This accumulated 1,000 Ohms resistive is off by at least one order of magnitude for a resonant choke at its peak (and for a fair BW overall). However, in the presence of that same 50V RF my beads simmer at a total 2.5W with any bead shedding all of 60mW - frosty.

The design paradigm that Roy offers is quite compelling and is certainly a shoo-in for fixed applications. For experimental work, the bead balun presents more flexibility in trade for modest performance and easier/quicker installation. If you invest in enough beads, of the right formulation, placed along the line to resolve unusual boundary conditions; then you have a very robust solution.

I own a portable DX-398. I purchased 100ft. of 22-gauge hook-up wire from RS. My plan is to connect the wire to a nearby tree about 80ft away from my upstairs window. I'll then attach the wire to an 1/8 F Jack or clip to the whip. My questions are these: I could run the wire along a second floor railing instead but this would only be about 25 feet and have 3 90degree bends in it. It would look better and be more secure than the run to the tree. But would the latter setup be as good as an antenna? Also, I could run the wire from second story window up through a hole in the ceiling and run the wire across my large attic - probably a 50ft run but inside. Most secure and looks the best but would it be a good antenna? One other thing is if I do string the wire to the tree, I'd probably want to wrap the wire around my second story railing for mechanical security. Does wrapping the wire around something ruin the whole idea of a "long" wire? Anyway, thanks in advance. RG

Source record: 136063

Regarding ferrite core baluns -- there are many ferrite materials, each with different characteristics. But they can be divided into three general groups. Using the Fair-Rite Corp. type designations (also used by Amidon), these are the 70 series, type 43, and the 60 series. You can find impedance vs frequency curves for these types at the Fair-Rite web site. Over most of the HF range, the impedance of 70 series ferrites is essentially resistive and relatively high. The impedance stays fairly constant over an extremely wide frequency range -- a winding on one of these looks like a resistor. This makes them favored for such applications as wideband transformers. They also make excellent baluns unless there's enough power to cause overheating (more about that in a minute). 60 series ferrites are primarily inductive at HF, and maintain a reasonable Q. A winding on one of these will resemble an inductor, and the loss will be very low compared to the other types. The problem is that you won't have nearly as much impedance as you will with the other ferrite types. Type 43 material is in between. It has a low Q in the lower HF range, and is primarily resistive at the upper end. But its impedance is somewhat lower than 70 series material. Overall it's less lossy than 70 series and more lossy than 60 series. Type 43 is widely used for EMC reduction, and a wide variety of core sizes and shapes are available in this material. Other vendors have comparable materials. For balun purposes, materials with similar initial permeability will have similar characteristics.

Powdered irons have much lower loss than ferrites, but also have much lower impedance per turn squared. The popularity of F-gazillion-2 baluns notwithstanding, powdered iron is seldom the best material to use.

Loss is I^2*R. If a balun is doing its job well, I, the current you're trying to choke, is small so the loss is low even if R is high. It's an impedance matching situation -- if the balun R is very low or very high, loss will be small. (High R results in low I.) Of course if balun Z (R, X, or a combination) is low, it won't be very effective.

If you're running 100 watts, one dB of loss is about 25 watts. You can probably imagine what would happen to a small ferrite core if it were dissipating 25 watts -- it would likely explode. The fact is that a decent ferrite balun, even on 70 type material, will typically result in only a small fraction of a dB of loss. So you don't need to be concerned about that aspect. The problem is that a small fraction of a dB is still a lot of watts if you're running a kW. So a ferrite core balun can get way too hot even when its loss is entirely negligible from a signal standpoint. In those cases, type 43 is better than 70 series, and you might even have to settle for a less effective balun wound on 60 series ferrite. But if your balun doesn't smoke or explode at a 100 watt level,

you'll never notice the loss on your signal. I find a one inch or so 70 series or type 43 core to be fine up to at least 300 watts, feeding a reasonably matched antenna.

As for RG-174, I often use a similar cable for portable operation, especially on 40 meters. The stuff I have is the same size as '174, but it has a solid center conductor. Standard '174 has a stranded Copperweld center conductor. And although the copper makes up a sizeable fraction of the wire diameter, the strands are so tiny that the current begins penetrating into the steel somewhere around 7 MHz. So at that frequency and below, the loss can be greater than you'd expect. I recommend measuring the loss of RG-174 if a very long piece of it will be used at the lower end of the HF range, since its loss might be more than a simple extrapolation of the higher frequency loss would indicate. The copper on the solid center conductor of the cable I have is thick enough that it's not a problem. As for power handling, I've had no trouble at 300 watts with a reasonably matched load. I personally think a lot of people have been conned into using bigger and more expensive coax than they need. Like the sign over my desk says, "Anyone can design a bridge that will stand up. It takes an engineer to design a bridge that will barely stand up."

From: n7ws@nowhere.com
Message-ID: <3d669a78.11744720@news.triconet.org>
Source record: 136064

On Fri, 23 Aug 2002 20:04:46 GMT, River Gravel <tanked@free.net> wrote:

Last things first. A "long wire" antenna is usually defined as being long with respect to the wavelength, thus having some directional characterizes. What you are proposing, in any of its manifestations, is a "random-length" wire.

That said, the "best" version from an all round performance standpoint would probably be the wire run to the tree. Obviously, from an appearance and mechanical viewpoint, it is probably the "worst" antenna. If you go this route you need to account for movement of the tree, as your AWG 22 wire is very fragile. Wrapping it around the railing is probably not the best either, particularly if it is a metal rail. A possible, although not very elegant solution to both issues would to use something like a light tension bungee cord that would save the wire and serve as an adequate insulator.

The other two alternatives are difficult to analyze without knowing the construction of the railing and/or walls and roof of your home. A lot of hams have some success using indoor antennas for both transmitting and receiving so depending on your circumstances this might be the "best" compromise antenna.

Whatever you do, be careful. I'm sure you are much old than I was when I started SWLing at about age ten. Having no mentor at all, I risked life and limb climbing ever higher in a flimsy tree thinking that a couple of more feet in wire height would surely improve signal strengths immeasurably. Fifty years later I think I know better.

|I own a portable DX-398. I purchased 100ft. of 22-gauge hook-up wire
|from RS. My plan is to connect the wire to a nearby tree about 80ft
|away from my upstairs window. I'll then attach the wire to an 1/8 F
|Jack or clip to the whip. My questions are these: I could run the
|wire along a second floor railing instead but this would only be about
|25 feet and have 3 90degree bends in it. It would look better and be
|more secure than the run to the tree. But would the latter setup be
|as good as an antenna? Also, I could run the wire from second story
|window up through a hole in the ceiling and run the wire across my
|large attic - probably a 50ft run but inside. Most secure and looks
|the best but would it be a good antenna? One other thing is if I do
|string the wire to the tree, I'd probably want to wrap the wire around
|my second story railing for mechanical security. Does wrapping the
|wire around something ruin the whole idea of a "long" wire? Anyway,
|thanks in advance. RG

Naaahhhhhh Tom, I'm talking about getting a negative reading on my field strength meter. I should be able to do that if I have negative power available.

My multiband inverted V dipole (40 ft up) is not doing great on 80 and 160, for the usual reason and I can't turn my property into an antenna farm. So I am still looking for a solution.

What is the story on the mobile HF antennas, like the screwdrivers? They are close to the ground and are said to be tunable to low SWR. If I buried my truck in my back yard (or a heavy 20 ft X 20 ft. stainless screen) and stuck one of these right on top, would I be able to DX on 80 and 160?

See, e.g., the Larry KJ7U, which appears to have the best materials:
http://www.kj7u.com/default.asp
http://www.eham.net/reviews/detail/2339

Or is this a case of "if it looks to good to be true, it is too good to be true."

Where is the 500 watts going? Do these things propagate any significant RF or just heat themselves up?

I've said the only reason power is negative is direction, Roy. Seems to
me, negative power is positive energy flowing in a negative direction.
Thus, there seems to be no such thing as negative energy, i.e. there seems
to be only negative directions. So I am asking for a real-world demonstration
of actual negative energy. It's the difference between -(+joules/sec) and
+(-joules/sec) where the first sign indicates the direction and the second
sign indicates the quantum nature of the energy. Where can I find some of
this negative energy? Does anti-matter contain negative energy?

Chances are that your AM-BCB 'antenna' is a ferrite rod inside the
radio. You can couple to it with a couple turns of wire around it.

That is no more negative stored energy than a lump of iron sitting
in your garage. By your definition, everything physical would have
to be a source of stored negative energy - until you got to the hottest
plasma that can possibly exist.

Ice cubes in my freezer still have a positive energy because they
are above absolute zero. At absolute zero, they have zero energy.
Now someone please tell me how to obtain negative energy. How does
anything get below absolute zero?

That parses fine. Now, you can change some back to using the brackets
and braces, if you wish - as long as you keep the pairs matched.

I thought that the above was what you meant, but was not sure as there
were a number of ways to correct the parsing on the original equation.
And I was too lazy to look it up.

|Hm, that limits it to 2:1 SWR or less.

If I'm reading the same section of the Bird manual, I think what they are attempting to communicate is that achieving Pr < 10% (SWR = 2:1) is "good enough" in the commonly accepted case.

Also, 1% (SWR = 1.2) is approaching the accuracy limits for a single element but lower values can be measured by using two different elements.

Just to complicate matters a bit (shame on me - I can't help it ;-)
I'll point out that physicists do consider the concept of "negative
temperature" to be a valid one. It's possible for a closed system to
be described by a negative temperature... but, oddly, it's _hotter_
than the same system at any positive temperature.

http://math.ucr.edu/home/baez/physics/ParticleAndNuclear/neg_temperature.html
is one place to read about this rather strange condition.

'Tain't relevant at all to "negative" or "reflected" power on a
transmission line, as far as I can see.

Hi Cecil,

Again, the inference does not match the implication; but it does
reveal the quiz is wholly devoid of life.

Your ice cube has lots of energy at ANY temperature. Open that
freezer door and I am quite sure if it fell to the floor it would
still exhibit the same power that stirred Newton to observe and put to
theory more than 300 years ago. In this day and age it is the energy
we call potential (as opposed to the kinetic, when the ice cube
falls), and for those who cannot relate outside of an electrical
paradigm, energy for centuries simply meant gravity (still does - even
if you cannot argue it correctly).

This shows how poor a metaphor ALWAYS is when applied to an argument.
The metaphor typically fails at the wrong time and pulls the argument
it is weakly buttressing, down with it. The perception is much like
the observation of a broken food tray in front of you on an airplane:
If they can't maintain the tray, how dutiful are they with the wings?

|Naaahhhhhh Tom, I'm talking about getting a negative reading on my field
|strength meter. I should be able to do that if I have negative power
|available.

Turn the damned meter upside down. Now the greater the negative power, the more the meter pointer moves to the left.

Or as Einstein might have said, "It's all relative."

My tried and true advice:
Make it as high as you can,
make it a LONG as you can,
Use a tuner,
Use a ground at least as long.

That's right. In his book, _Quantum Theory_ David Bohm writes, "In classical
mechanics,
the energy of a body is defined in terms of its ability to do work on other
bodies. (Work is
defined as the product of the force exerted by the one body on the other and
the distance
through which this force moves.) Since the preceding definition determines
only changes of
energy, the zero of energy can be chosen arbitrarily at a convenient point."
Later, he expands
this definition to include electromagnetic energy in space which can also do
work on bodies.

Another possibility is a small pully from the hardware store. Attach it to the tree, and let your wire hang through it, with a light weight on its end. Attach the other end firmly to the house. Then the wire will "give" when the tree moves. Radio Shack also has antenna insulators you can use to isolate the wire from the tree and house. Run the wire straight to the random-wire attachment on your radio, and the setup should work nicely.

I want to build a Walking Stick antenna to replace the dummy load on my H-T. I intend to use this in search and rescue work where it is critical to have good communications. I believe that the antenna I have in mind would fill 2 needs. First it would increase the effective range of my H-T, and second it would be a usefull tool as a walking staff.

Does anyone know where I can get advice and or plans for building one of these?

Any guidance would be appreciated.

You should have mentioned your use for the rig in the first post.

If it's mobile, the Diamond HV-7A whip covers 10-6-2-440. I couldn't tell you
how good it is, but it is rated for those bands.

>I am putting 100 watts at 80M into a shortened inverted-V dipole with
>center 40 ft up.

Some questions:

- How "shortened" is this dipole? (100 feet? 80 feet? 66 feet?)

- How is the shortening done? (Loading coils? Traps? Simply cutting the wire short?)

- What is the feedline and matching system?

- How high are the ends?

>The only contacts I have been able to make are after
>dark to a densely populated area 20-30 miles to the west, behind a
>nearby hill that blocks line-of-sight to the contacts.

80 meters is fairly quiet during the daylight hours. After dark is when things come alive.

>Is my signal going straight up and these folks are seeing scatter off
>my pillar of RF? Will scatter travel that far?

Most of the signal from an 80 meter dipole or inverted V will be radiated at high angles, but the idea that it's all going "straight up" is a misconception. Here's proof:

Using EZNEC (Demo version), I modeled a full-size 80 meter inverted V over medium ground using the 'high accuracy' ground mode. I set the center (feedpoint) at 40 feet above ground and the ends at 20 feet. wire length was adjusted for resonance at about 3.6 MHz.

At right angles to the wire (most favored direction), the radiation is:

90 degrees (straight up): 4.93 dBi
60 degrees: 4.13 dBi (0.80 dB weaker than straight up)
45 degrees: 2.86 dBi (2.07 dB weaker than straight up)
30 degrees: 0.40 dBi (4.53 dB weaker than straight up)
25 degrees: -0.87 dBi (5.80 dB weaker than straight up - just under 1 S unit)
20 degrees: -2.53 dBi (7.46 dB weaker than straight up - about 1.25 S unit)

The signal radiated at 25 degrees is only about an S unit weaker than the signal going straight up. But a signal leaving the antenna at 25 degrees will come down
roughly 900 miles away on the first hop.

I think perhaps the problem may be that your 100 watts isn't all getting to the antenna. Please give some more details on this installation.

wayne
i really dont think it would help cause on VHF and UHF you need height as much as you need gain so an antenna at ground level wouldnt be of much help since most S/R type folks wear hardhats why not rig a dual band 1/4 antenna on the top of it that way your body height will be higher than the walking stick and you can leave the HT on your belt and use a speaker mic
you would look a touch goony sorta like a red unicorn but you would be heard and keep in mind that an HT doesnt hold a charge more than a couple of hours in the 5 watt mode which is what you would need to be heard with any antenna you choose
good luck

Ken,
If the screwdriver antenna has 'enough' coil
it should work on 160 meters. Probably not the
'best' in the world, but it should work. Your
truck may not be enough 'ground' or counterpoise
for 160m though. A couple'a'few radials as long
as you can make them certainly wouldn't hurt.
The same holds for any mobile antenna, not just
for the screwdrivers.
'Doc

Hi Ken,
Don't listen to the folks who say you have a cloud warmer. I have a slightly different configuration - a long dipole with the arms at right angles along the sides of my lot, the center up maybe 35' and the ends up maybe 15'. But it works the whole state of Maryland and some of Pennsylvania during the daytime. I know because I run an early evening net using 50 watts. Plenty of sunshine during the summer. During night-time hours, I can work the whole east coast.

I would bet that there is some lossy component somewhere in your system (a low SWR could be a symptom of a lossy system). Thoroughly check your system out. One simple test is doing DC resistance checks on your feedline, antenna wire, and connectors.

Hi all,
I have found screen door springs, you know, the long ones about 1/2
3/4 inch diameter, work great. Just use a piece of nylon rope or
heavy fish line on an insulator to attach the wire.

>-BM

Agreed. A good way to tell is if you collapse the telescoping antenna
and the signal input strength does not change, you are operating off
of an internal ferrite bar. Physically put your palm on the radio in
various places and when the signal strength suddenly doubles you will
know approximately where the ferrite bar is .

Jean Cesario, F8BXG, wrote:

> I'm wondering about losses in antennas made of standard "domestic"
> stranded or solid copper wire, insulated with polyvinyl chloride.

As Richard indicates, you will not notice any difference in loss
when using the different wires as _antenna_ wire.

What quantitative data I have is safely packed away
in boxes that I brought home from work when I retired last year.
However, some qualitative notes follow...

You _will_ notice a difference when using pairs of wires
with different insulations as a transmission line.
For instance, polyethelene is a very good insulator
with low loss and stable characteristics for a very
wide frequency range (audio to television twinlead)
and with time. It is a relatively soft material.
PVC is a tough material and is often chosen
for low frequency use (AC and outdoor telephone)
where it may be subjected to physical abuse,
weather, ... However, it is not a good insulator
in that its characteristics vary with frequency.
I once had the chance to salvage several reels
of telephone drop* wire with 19 1/2 AWG
copperclad steel wire and PVC insulation.
Some quick calculations indicated
the impedance was in the 100 ohm range
and that it _might_ be useful as transmission line.
Then I learned about its very poor performance
at radio frequencies and passed on getting the cable.

My layman's understanding is that the PVC molecule
is polar, meaning it has - and + ends. When
it is excited with rf , loss results when the molecules
vibrate. This is not noticable for practical purposes
when used as a conductor for receiving antennas.
When the wires are paired for a t-line,
the characteristics of PVC will affect the performance
for transmission purposes where loss counts more.

(Subject to correction and a more clear
explanation by real experts... It is getting late here
and brain cells are experiencing loss.)

Cheers, 73,

Ron McConnell
w2iol

* "Drop" meaning the drop from utility pole to house
where it must survive squirrels running along it,
chewing on it, rubbing against tree limbs...
Thus PVC and copperclad steel.

3759. Re: Hustler 6BVT vertical

Newsgroup: rec.radio.amateur.antenna
Date: 2002-08-24 05:20:24 UTC

Source record: 136000

Thanks for the info. I've never had a vertical but know how they can
be tricky on using or not using radials. IN the situation I have
facing me, the only option will be to lay radials down. I've read in
users reprots and the manual to have the radials insulated from the
ground. So it would require to lay insulated wire on the ground and
seal the end of the wire so it won't come in contact with the earth.
I have to investigate that further to make sure it's true.

Yes indeed. A vertical dipole is better than a 1/4 vertical. It
would be nice to make a more effecient vertical.

I ran into much the same problem, except that I'm not even able to try a dipole for 80. (Multi-unit apartment complex.) I decided to give the Isotrons (40 and 80 for me) a try; they've received decent reviews in the magazines and on eHam. (Mine arrived today; I hope to get them on the air this weekend.)

While they're not cheap, they are a darn bit cheaper than a good screwdriver type antenna, *and* they don't need a ground plane.

http://www.rayfield.net/isotron/

Remember, mobile installations have much stricter limitations, such as height and wind loading, that home installations don't have.

Maybe you can consider making a base loaded vertical for 80/160? 30' of aluminum tubing should put out a respectable signal.

> Thanks!

It most likely uses a small ferrite bar antenna inside the radio. You
may notice that it is somewhat directional according to how you turn
the radio.
Adding a wire antenna to that whip won't do a thing as the whip should
be for FM only, unless it also includes shortwave bands. Your present
antenna really should be good enough if you are hearing a good bit of
noise when a station is not tuned in. About the only way to really
improve it is to make a larger loop antenna of a few turns, and then
place the radio up behind the loop to couple with it. You will also
need an old variable cap to tune the loop to resonance. Any old 365 pf
BC cap will do from an old radio. You don't have to make any direct
connection from the loop to the radio. The radios ferrite antenna
becomes the coupling loop. You will notice a certain spot where the
signals are the strongest. Thats the distance you want to keep it from
the loop. This radio/loop combo is quite directional with good nulls.
The nulls are broadside to the loop, and max signals inline with the
loop wires. Opposite from the operation of a large 1 wave loop. I have
one loop I've been using quite a bit with my 706 for MW use. It's a 16
inch dia circle , on a round plastic frame with 12 turns of wire. I
have a two turn coupling loop about an 1.5 inches behind the main 12
turn loop. You can actually feed the 12 turn loop directly, but I
think I get a slightly cleaner pattern with the coupling loop. I have
it mounted on a turnable base so I can turn it to null or peak
signals. MK

> to DX on 80 and 160?

You would be much better off with some kind of simple vertical like an
inv L, T vertical, or whatever. The average mobile antenna on 160m
might be good to do 1.5-3 % efficiency when mounted on a large car or
truck. An antenna such as that will require a very good ground system
to work in a backyard on the ground. The shorter the vertical in
wavelength, the more critical the ground. If you can string an inv L
up through a tree ,even with a few number of radials, you would be
much better off. But yes, you can work dx with a vertical.
Many times a good vertical like a bugcatcher on a large truck could
outdo your 40 ft high inv vee to far off distances. I've seen that
happen even on 40m at night. I've worked quite a few mobiles on 160m,
but none dx. But thats more due to my limitations than theirs...:(I
don't really have too good of receiving antennas on 160m. I've
listened to Tom W8JI many times working dx, and I almost never hear
the stuff he works. I'm talking a total blank. Trying to hear that
stuff on the average transmit antenna is tough. MK

3764. Using coax shield for long wire antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2002-08-24 12:47:51 UTC
From: emergencyradioserv@yahoo.com
Message-ID: <46060eb3.0208240447.51029cd3@posting.google.com>
Source record: 136005

Anyone have any experience good/bad with using the braided shield of coax as a long wire antenna? I have a large roll of RG-59/U with copper braid and a LARGE lot to run it over. I want to be able to monitor (no transmitting) on 160 meters and below. I thought of using the shield as the antenna and a local ground at the radio. (Lightning protection will of course be provided as well.

Is there any advantage to doing this due to the potentially larger diameter of the antenna rather than using simple wire? I know there will be more ice loading on it but another thought is laying on the ground and using it as a LW antenna.

Any thoughts or input welcomed.

Thanks Bob

I have used the 4BTV with a 80m KW resonator basically its now a 5BTV. Bought in in 1975 when licensed as a novice took it down a few years later and been in storage until 2000 when I got back into the hobby. Now have a Cushcraft A3S which hears better and works better. Mine is ground mounted with no radials using 500W was a must for DX. The soil conductivity in South Florida seems pretty good and where the antenna is mounted does't lend its self for radials. Don't get me wrong the antenna did work a lot of DX and if you are space constricted its not bad, better I am sure with a counterpoise. This antenna is easy to take down just by loosening the bottom clamp and removing the antenna from the base unless you want to tilting over for stealth reasons. A few times during hurricane warnings I have taken it loose from the base and split it and tossed it in the garage. My tower is a tilt/crank up for those reasons.
80 meter performance isn't so great

Derek,
No need to worry, it's just that some days it's
really hard to put up with nonsense. I don't send
my partner for groceries any more. He's a miniature
schnauzer, and his tastes are sort of odd compared
to mine. I'm not sure what HRT is, but if you can't
get it with food stamps I don't need it. Can you
recommend anything for old broken bones, and stuff like
that? I'd sure appreciate that! Maybe something for
baldness? I don't need any more hair, but going to
a barber sure is a pain since my last one quit. She
was really a pleasure to have cut my hair (wink, wink).
Thanks again for your concern Derek, it's nice to
know you care. I think I'll print it out so I can
show people when they drive by. You know, sit'n and
rocking in my rocking chair, on the front porch. I'll
bet they'll think it's nice too...
'Doc

3771. Lightning Effects Questions

Newsgroup: rec.radio.amateur.antenna
Date: 2002-08-24 17:41:11 UTC
From: Robert Rose <rgsrose@tiac.net>
Message-ID: <ak8gmg$23i$1@slb5.atl.mindspring.net>
Source record: 136012

Hello:

I guess the subject of lighning protection, induced voltages, and the like
is a favorite topic herein.
I've read up, a bit, on it, but still have a few basic, and a few applied,
type questions.

A very confusing subject, all in all.

Hope the following isn't too confusing, so let me ask, please:

I have just installed a new discone in my attic (receive only).

Having read the great posts on the subject, I now appreciate the fact that
the discone will work just as well,
with or without a separate ground up at the antenna end.

But-

a. The single rod vertical element protruding from the top of the Discone
ends only about 1 inch from the interior surface of
my attic's roof (essentially the roofs high point).

I am therefore wondering if this "might" make the antenna more prone to
attract a direct lightning hit?
Or, does the roof actually provide "some" protection (due to its being
something of a dielectric?) ?

If so, why? Differences for a wet vs. dry roof?

b. Would it still be a good idea to ground the antenna mast (which would
also ground the elements) to a water pipe in the attic?

-Does the possibility of a strike, or induced voltages from a nearby
strike, go to zero if the coax is unplugged from the receiver?
(which is what I plan on doing, but one sometimes forgets)

c. A theoretical question: in the general sense, does a grounded mast help
prevent a counter charge from being developed beneath a charged up cloud, or
merely provide a well defined path for a lightning bolt to travel to ground?

d. From looking at some catalogs, I see the in-line coax lightning
protectors seem to come in two flavors:

there's (a) the type from Alpha Delta which provides a separate lug
for grounding, and (b) most of the others which
apparently funnel the charge, when the spark gap breaks down, to the
coax shield.

what I'm wondering about, is for for (b). The charge would then
go directly to the chassis of the radio, and would
then reach ground via the chassis' ground.

As it may not be an actual strike, but perhaps a lower induced
voltage of just enough to break the spark gap,
what would this do to the radio (e.g., the chassis being raised
momentarily to 100 V, or so) ?

Are both types just as safe and useful?
Any caveats?

Thanks,
Bob

Go to Radio Works and take a look at the 16m Beam Special Carolina Windom.

I've used one of those for several years, and find it simply the best way of getting on 160 from limited space. The Beam Special requires about 100' or so of horizontal, and the ends can be bent down.

On 160, it becomes a "shorty" veritcal with top loading. It's a tough match apparently, because Jim derates the ant to 500 watts on 160 to keep from overheating the pot.

Mine gets out very well, and my vertical feed hangs straight down. That's another almost requirement. The 32' active element of feedline hanging straight down, and being in the clear is important for radiation purposes.

The nice thing is that the 160m Beam Special is great on all freqs above 160m. It will match/load on most without a tuner. Give it some thought.

For all the usual reasons, of course.

>b. Would it still be a good idea to ground the antenna mast (which would
>also ground the elements) to a water pipe in the attic?

As you most likely have a plumbing vent that will be higher than your
antenna, and that it is already a conductor (maybe plastic which
invalidates everything here) to ground, lightning is far more likely
to seek that path (no warrantee against capricious strikes is made nor
implied)
>
> -Does the possibility of a strike, or induced voltages from a nearby

That lead up into the sky is a short circuit to the charges stored up
there. You may not offer a ground, but it still remains a preferred
path over insulative air.

>
>c. A theoretical question: in the general sense, does a grounded mast help

Be thankful if it does "merely" that and skip the philosophies of charge.

Hi Bob,

Skip the arrestors too, concentrate on a safety ground first (ask a librarian for the local electrical code).

Take pause for common sense. I would bet that you already have wire in the attic (going to the doorbell if nothing else) that has yet to be struck by lightning. Same must be true of nearly every neighbor within view. As an attractant to lightning, your antenna is barely going to poke 3 feet above these other strike magnets (and as magnets they are pitiful).

This is all pretty facile to shrug off the risk indoors, but if you were tempted to hike this up outside, it might be a different story. Being different doesn't mean that the risk is catastrophic, it means that your ground issues have moved outdoors - if you ignore them there, grief will find its way indoors.

Bob,
There really isn't any advantage to using braid as an
antenna, and there are a few disadvantages. The primay
disadvantage is that weather tends to 'eat' copper braid
fairly quickly.
The diameter of the conductor makes very little differnece
at HF, especially on 160 meters. Any conductor that is
large enough to hold up it's own weight will work as well as
any other conductor in almost all cases.
Using RG-59/u for the conductor will work. It may not be
the 'best' use you could put it to, but it should certainly
work.

Doctor Cohen, (Chip)
What is the secret that you,Hately and others have to get so much
attention to your antennas ? I imagine I have seen so many pages where
your antennas have been scrutenised, disected, delved into, deep
searches for inconsistencies and errors that it could easily rival
'common mode' discussions.
If I remember correctly, the torrent of discussion put you in line for
a hefty grant from the government which wasn't too bad and I think
Hately got government assistance in the same way. In both cases the
government took an interest in your work where from others all you got
was derision. So tell me Chip, do I have to be rude, call everybody
names and get everybody upset so that they get in line to try and chop
me off at the knees? Staying calm and polite is not what people are
looking for, is it just a fight that get their juices running?
All I have is a little ferret named doc who keeps snapping at my heels
but nobody of any consequence.
So what is the secret that you and Hately have ?

Sounds like LF parasitic oscillations in a solid-state transmitter.
Harmonics
would not fall in the same band at nearby frequencies. Perhaps the
antenna reactance was just right to cause instabilities?

Bob,
Having an antenna in your attic isn't going to make
your house appear more attractive to lightning. You
have the exact same chance of being struck by lightning
with or without the antenna, it will affect that 'chance'
in no appreciable way at all.
Like any antenna, the one in your attic may have fairly
large currents induced in it from near by lightning strikes.
It isn't a bad idea to disconnect the antenna from equipment
when there is a storm near by. Shorting the connector to
ground isn't a bad idea either, but not one I'm convinced is
necessary.

Hi there!

Our new Magnetic Loop Website are now in english available.

http://www.magnetic-loop.de

There were a lot of request to us, to setup the software to english language.
This is now done. There is also the e mail notification now working, if someone replies
to your message inside the board. For this you have to register with username and
password...a very useful function , if you re not every day there.

We would be happy to get your questions, hints and information in our Board :-)

just visit our NON commercial and no ads website http://www.magentic-loop.de

Thank you very much :-)

Andre

Mr Unwin:

I have nothing to do with this person who signs under 'fractena@yahoo.com'. It is not me. It is no one I know of.

I do not know who Mr. Hately is, nor am I in anyway interested. Nor do I seek to know why you have sought such an alleged association.

I do not discuss any personal matters here. Also, your facts are incorrect, and I will not attempt to understand why they are even posed in this antenna forum.

If you have a friendly, and factually based question along a topic I have already discussed, I will be most happy to respond to you. If not, kindly understand that I do not believe that expanding upon what you interpret as a impersonation should be discussed.

I wish you a most pleasant weekend, and extend that salutation to others here.

73,
Chip N1IR

Seconds on both the cloud warming and the likely trouble spot. I have a 96 foot dipole at 40 feet fed with balanced line and a tuner. During contests I have made several Pennsylvania-California contacts on 75 meter SSB. If I listened to the purists I wouldn't have even tried 75 meters.

What exactly is your setup, Ken? We should be able to help you troubleshoot it.

Hello,

Your signal is not going straight up, but its bulk is going at very high launch angle. In addition, the pattern down at 10 degrees-- a typical angle sought for DX-- is approximately 20 dB down from the high zenith gain, assuming your ground is between 'good' and 'poor'. I suspect you are also dealing with losses from shortening.

Do you hear DX in the DX window? If not, and you hear others working it in your area, then this is surely the case.

Sorry I don't have better news.

From: ps8sj@hotmail.com
Message-ID: <3375983.0208241240.766e7d92@posting.google.com>
Source record: 135928

Hi guys,

I am a newbie in the antenna trick, I am developping a new antenna system.

Can I parallel two antennas, (KLM 6 el Yagi & TH7) feeding them direct with
two 52 ohms cable into a TL922 amp ?

In the normal pratic split power as toroidal or Wilkinson circuit can match the 52 ohm antennas with the 52 ohm source

Teorically two 52 ohm antennas feeded each one with 52 ohm coax cable, connected directly in parallel are seen from the TL922 as a 26 ohm load.

The SWR seen from a 52 ohm source is 2:1, but if the source is an amplifier
with a tank circuit that can load the full power into a variable output load why I need to use a split power ?

I think that if an amplifier can load full power into a 2:1 SWR antenna, usually
antenna on 80m from SSB to CW portion or on an 10m Yagi always from SSB to CW freq. where the impedence can be 26 or 104 ohm, why it cannot load into a parallel antennas ??

Is there some problems, other then the antennas are not equal, and so may be
some load difference due the fact that they are not only resistive, that could
avoid this kind of coupling ??

Un abrazo

rodiho

There is no need to 'insulate the wires from the earth' if you are ground mounting the vertical antenna. The wires couple to the earth and are part of the 'ground screen'. In fact the wires should be buried just under the surface. Slit the grass and stick it in.

Perhaps you were thinking of say a 1/2 wave Gap, linear loaded jobber. This one does have three insulated wires laying on the ground. But I don't think this is what you mean.

I have an Alpha-Delta DX-LB+ inverted V shortened multi-wire, loaded
dipole with center at 40 ft., a 100 ft. RG-8X feed line, an MFJ-986
tuner and an FT990 radio.

Testing shows I am TXing on a frequency near antenna resonance on 160M
-- where I have an untuned band minimum SWR of around 2.0 -- tunable
to 1.0. At the ends of the band -- where I am not TXing -- SWR is
around 5.0.

The radio shows full power to the antenna, and a continuity tester
shows an open circuit on the feedline between the sheathing and center
conductor.

My two cents:

1) The short is due to the balun and is normal (that's a DC short);
2) Your antenna is too low for DX launch angles;
3) You asked about 80M and you gave info on 160M?:-> Typo?

>

>
Bingo, there it is, there's my conceptual problem. What happens in the
case of a 1:1 balun, air or ferrite core when the antenna is not a
"reasonable" match with 50 ohm coax? What's the definition of a
"reasonably matched load"?? Take the case of a G5RV. They can present
swrs which are all over the map but are still within the tuning range
of the average ATU. Which is "good enough" in most ham's minds.
>
>
Assume that the swr at the feedpoint is 6:1 and that it's resistive on
one band or another. The feedpoint impedance could be either 8+jï¿½ or
300+jï¿½. The proper balun under these conditions should be a 6:1 unit
connected one way or the other.
>
>
The average ham goes out and pops the usual $40 for one of the usual
store-bought G5RVs of which F-gazillion-2 are in use. They come with
some kinda balun, 4:1 or some such at the coax connector. Lousy match
with the balun no matter how you cut it. What's going on in those
baluns? What are the losses under these conditions? Is there a useful
decrease in losses with an air-core balun a la Heath vs. a ferrite
core balun? My tummy tells me yes and this is where I was orignally
coming from when I posed my question about how to wind air core
baluns.
>
>
Seems to me it gets even worse when "they" use a 4:1 balun to feed an
end-fed wire.
>
>
When cometh the point when one simply sez to hell with this
transformer stuff, just kill the circulating currents with a coil or
beads and take the coax losses?
>
>

I'm not shooting for "microlight" antennas, I like the idea of using
174 for winding compact baluns but I'd use 8X for the run from the
balun to the ATU. Any hints on the minimum allowable coiling diameter
for 174?

From Belden's data on 9204 (RG/59) max tension on cable is 344N, and its diameter is ~6mm.

If you planned to install it with 5% sag, WLL 25% of UTS, and to resist winds to 40m/s, the maximum span would be less than 4m.

You might achive higher UTS by effectively tying the innder conductor to the braid... but essentially standard RG59 has high wind resistance and low tensile strength.

> Is there any advantage to doing this due to the potentially larger

Ice loading will exacerbate the problem - additional gravitational force and additional wind loading.

I have an application (trombone capacitor) for which I might want to use Kapton (tm) as the dielectric. All the properties I've found look pretty good for my use. I haven't seen any specs on Kapton's friction properties tho'.

Has anyone had experience with using Kapton with trombone caps, or somewhere else that the material had to slide over another?

Not a typo. Just forgot which band I started talking about in the thread. Unsatisfactory results are same for both in that both have reasonable untuned SWR (around 2.0) where I am TXing (1.0 after tuning), and both produce strong skywave contacts at night no further away than 30 miles.

I should have also mentioned the 160M because alternate antenna solutions sugested for 80M aren't enough. E.g. the Carolina Windom "Beam" (now the 80) won't do it. The 160 is something like 265 ft. long, which I can't fit. They have a shortened 160, but I have no reason to believe it would be an improvement over the DX-LB+.

Does this have a line isolator (choke) on it? If so, is it at the feedpoint or down the length of the coax?

I WILL be switching to ladderline momentarily, but not to improve the
situation where I am TXing now. At these frequencies, I am near
resonance in the band -- around SWR=2.0 without tuner. At the ends of
the low bands, however, untuned SWR goes to around 6.0 at the radio.
I have been told here that this means SWR at the feedpoint of over 60
(which I verified) and 90+% line losses in the coax. Unfortunately,
the path I have for the ladderline is a little problematic and I await
some counsel from the ARRL as to do's and don'ts before I run it.

Hi Dan,

Thanks for th info and your right, the base would be part of the "ground plane" and insulating the wire would be fruitless. I had seen that on the review of the 6BTV on eham.net and 1 or 2 people "insualted" the wires from the earth surface and had better results and tuned easier. Makes you wonder. No need to worry about slitting the grass to bury radials. This is Las Vegas and there is no vegetation in the back yard, just small decorative stones, a cross between lava rock and pebbles, which can easily be moved, lay the wire, then cover. I still have a month or more before I make up my mind what I want to do and all of this info is helping quite a bit! :)

>- How high are the ends?

It is an Alpha-Delta DX-LB+
http://www.alphadeltacom.com/dxlb_ii.htm

Feedline is 100 ft. of RG-8X

Matching is done with an MFJ-986 at the radio.

Center is at 40 ft. Ends are at 20 ft. Ground slopes down 10% over
the length of the antenna. As a result, one leg is almost horizontal
and the other approximately 45 degrees below horizontal.

Hi Dale!

The reason for tilting it over would be for stealth reasons. I'm in the desert and I wonder how the performance would be with the extremely dry soil. However, you dig down about 1-1/2 to 2 feet and the ground is wet, actually very wet.

That's what I was looking for was how it performed on 80 meters. I wouldn't spend all of my time on that band but it would be nice to work a few new ones.

Like I say. I'm trying to decide which antenna I would like to put up. THe DX-77 or the 6BTV. A buddy of mine on the other side of Vegas has the DX-77, which I helped put up, and he loves it and he's able to work DX fairly well, even barefoot.

I've used some lousy 80m antennas but I can't imagine one that would
only reach 30 miles and no further.
From NC I tried loading up a window screen (in place) with my HX50 (no,
it didn't load well at all) and chatted with a guy in Mississippi for an
hour, solid copy.

Hi George

Teflon would work, but not quite as well. It has a dielectric constant of 2, while Mylar's is 3.2. This makes a big difference in the size of the cap. My design has good performance (at least on paper) from 15 meters down to 40, and I may be able to get something passable at 80 meters also. But if I go to teflon, I'll have to make the trombones a *lot* longer than I want to.

Can't say for sure. What is the application? I know you are trying to build coaxial capacitors but where will they be used?

Before we redesigned them to use Johanson tuners, one of our missiles used a "home-made" tuning post to resonate a cavity. To insulate the low impedance section, a single wrap of mylar tape was used. However, the missile was backfilled with dry nitrogen so moisture wasn't an issue.

3814. Magloop design question

Newsgroup: rec.radio.amateur.antenna

Source record: 135954

My design for a magloop has trombone capacitors (yeah, like everyone doesn't know that by now! ;^)

My question is: How much will the exterior piping of the trombones affect the antenna? Which is to say that I plan on having two sections approximately 15 inches on each side for the Stators of the trombone. This piping is planned to be on the inside of the loop.

When I hit the lottery I'm gonna get me a proper setup and make about three dozen baluns and measure all the parameters. Just to satisfy my own curiosity.

> I do, however, have some
>graphs of RG-58 flat coils of two lengths and various numbers of turns.

You just added another level of complication. When you say "flat coil", do you mean a single pancake layer like rope laid on the deck of a ship, or wound up in a hank as shown in the picture in the Handbook et al? I think there'd be some significant difference in resonant frequency and overall Z between the two.

>Of these, the best had just over a 3:1 frequency range at the 500 ohm

>of about 3:4, flat:solenoid for bandwidth.

Sounds reasonable. Two of the columns of the K1TTT data (the two I referenced) sure look like the same coax wound two ways.

>I do like the flat approach because it's fast, simple, and low weight
>and bulk.

Yup. No piece of PVC pipe adding weight, either. Just a couple of UV resistant ty-wraps.

>But there certainly is more than one way to make an effective
>air core balun. And if maximum bandwidth is the goal, other methods
>might well be better.

One thing all this points out is that there's no quick'n'easy 3-30 MHz magic balun design out there, whether it's coax, coils, beads or cores. All have their advantages and weaknesses.

It would be really neat to see how good or bad the old Heath B-1 really was. B&W sold those coils for years - all Heath did was package them in a nice box with instructions.
>
>Whatever method is chosen, though, I believe you'll find that the
>maximum bandwidth will be achieved if you make use of self resonance,

>and don't try to restrict yourself to the region where the device is
>inductive or to prevent resonance.

Agreed! All we really need is lots of X - whether it's capacitive or inductive doesn't matter.

Looks to me that what W3RV wants is a bulletproof balun for a half-size G5RV, to cover 40/20/15 and maybe 10. Me, I'd look at a trap or parallel dipole to do that job.

Got it mounted on the steel mast. Used a long bolt for standoff. Let the
ladderline drape down to the eave of the roof then ran the feed line to the
transmitter along the eave. I can get the SWRs down below 1:1. I'm quite
happy with the results. Thanks for all the input!

This would be an antenna application, so It would be in an enclosure, but unsealed. It wouldn't have to be constant in Dielectric constant (hows that for an contradiction), but would need to retain it's physical shape, ie no swelling. Voltage characteristics would need to stay put pretty much, or be overdesigned a bit. This darn thing will have almost 8KV across the cap when in use on 40 meters.

Thanks for the advice!

Robert Rose wrote:
"The single rod vertical element protuding from the top of the Discone ends only about 1 inch from the interior of my attic roof."

Radio towers with a flashing beacon at their tops are often hit by lightning. This does not harm the beacon because a lightning rod extends well above the beacon. The rod takes the lightning hits sparing the beacon. The beacon is well within the rod`s "cone of protection".

A lightning rod on the ridge of a house roof above and near a Discone antenna may (no guarantee) protect part of the house and the Discone antenna within its cone of protection.

Best regards, Richard Harrison, KB5WZI

Hyper-light-speed antenna

Abstract
A method to transmit and receive electromagnetic waves which comprises generating opposing magnetic fields having a plane of maximum force running perpendicular to a longitudinal axis of the magnetic field; generating a heat source along an axis parallel to the longitudinal axis of the magnetic field; generating an accelerator parallel to and in close proximity to the heat source, thereby creating an input and output port; and generating a communications signal into the input and output port, thereby sending the signal at a speed faster than light.

I sure would check out the feedline with an ohm meter for shorts. No antenna is as bad as the results you are getting.

I once made several contacts on a fractal 10 meter antenna on 75 just for grins. All of them in excess of anything your getting. Back in the old AM days, I talked further than that loading a 100 watt lightbulb with about 18 inch leads with an old DX-100.

My guess is that you have a short or open in the coax or a bad solder job on a connector. Check out the cables,and the connection at the center connection of the antenna.

Also check the continuity from the center piece to each connection to the antenna wires. To be this bad it has to be something simple.

I am Huntington on the north shore of Long Island, where the land
drops to meet Long Island Sound. My house is on the east side of a
neck that extends to the north.

My shack is actually on the hill, which rises at 10% to the west and
crests approximately 30 ft. above the center of my dipole.

To the east the topography is roughly flat for 100 miles and then
Atlantic Ocean.

To the north is flat terrain for 10 miles then the hills of
Connecticut behind Norwalk.

hey randy
i think the only way to go in your situation is to use hamsticks as a dipole on something like a musicians mic stand
the makers of hamsticks also make the dipole mount to screw two of the same band hamsticks in it and attach it to the stand and you will be off and running on what ever band the hamsticks are tuned for
the other antennas you listed all need some kind of a ground system and unless you care to bound in a ground rod and hook it to the mount i think the hamsticks will do just as well and they are cheap only 25 eash or so
good luck

|>But if you're using coax, especially a long run of coax, the loss
|>might be quite substantial, and you'd be better off going to ladder line
|>and/or lengthening the antenna.
|
|I WILL be switching to ladderline momentarily, but not to improve the
|situation where I am TXing now. At these frequencies, I am near
|resonance in the band -- around SWR=2.0 without tuner. At the ends of
|the low bands, however, untuned SWR goes to around 6.0 at the radio.
|I have been told here that this means SWR at the feedpoint of over 60
|(which I verified) and 90+% line losses in the coax.

I don't know how you "verified" 60:1 but I doubt that it's anywhere near there.

Without the dimensions of the wire on the far side of the "ISO-RES" it's hard to try any modeling of your situation. However, the ISO-RES seem to be nothing but rf-chokes, offering a bit of inductive loading on 40 and a lot on 80. They also have to be extremely lossy, which strange as it seems, works in your favor as far as bandwidth goes.

So... assuming that the real part of the impedance at 3.5 MHz is around 20 ohm with a bunch of capacitive reactance I poked these numbers into Dan's (AC6LA) "Transmission Line Details" program, a copy of which everyone should have. See:

http://www.qsl.net/ac6la/tldetails.html

Step 1. I selected the built-in parameters for Belden 9258 (RG-8X).

Step 2. I set the frequency to 3.5.

Step 3. I set the line length to 100 feet.

I set the load R to 20 and incremented the X value (in the negative direction) until the SWR at the input was approximately 6:1, which you say you measure. I can now read the SWR at the load (20 -j86) as about 9.3:1. With the power set to the default 100W, the loss data on the right side of the screen shows the power at the load should be about 59 W, or a total loss of ~2.3 dB, which is a long way from 90%.

The load Z that I picked was an educated guess. Since the antenna is low to the ground and much shorter that a half-wavelength long, the real part will always be much lower than a resonant length. Since the antenna is resonant higher in the band, the reactance has to be negative. You claim a 2:1 SWR at resonance which suggests 25 ohm for the real part higher in the band (I know not where).

This will drop somewhat as the frequency is lowered.

If you don't like these particular numbers, try something else (with the aforementioned limitations) but you'll find it doesn't make any difference.

Now that you're in the program, leave the load Z as is and go to Step 1 and select Wireman 554 ladder line.

Looking at the new loss figures you see that you now have 85 W at the load or a total loss of only about 0.7 dB. Looks like the way to go, right?

Well, not so quick. Check out the 50 ohm SWR, it's 80:1. The real part is near enough to 50 ohm that if the reactive part was tuned out the SWR would be acceptable. The problem is that if your tuner is the now common hi-pass tee with two series caps and a shunt inductor, you can't match this load.

|Unfortunately,
|the path I have for the ladderline is a little problematic and I await
|some counsel from the ARRL as to do's and don'ts before I run it.

Don't

Depends on where the losses lie. If the intent of the balun is to
maintain a radiation pattern then the balun internal losses can be
miniscule vs. the "losses" associated with a radiating feedline to a

highly directioanl antenna. But that's not the point at the moment.

True, but then ya have a heavy beast of a balun which would not be
suitable for the pack 'n go antenna I'm trying to pull together. My
thrust is to come up with a workable combination low weight, minimum
bulk and "enough" choking at the 100w level to do a decent job given a
40-15m mutiband dipole. Or in a stetch a 40-10m antenna. Or a vertical
multiband 40m half-wave loop. Or some balanced antenna along these
lines. Looks like 500 ohms worth of choke at 7mHz is the input
parameter for "enough". Or maybe to hell with any balun in these kinds
of inherently non-critical applications.

Hi Brian,

Mine is less than 2 OZ of ceramic on one foot of RG58. How does that compare to the weight of 10' of coax in an air wound balun? I use it every field day without trouble and I also bring the same amount of beads distributed over 40' of coax.

Thanks Dick and Ron for pertinent opinions. You comfort my own thinking, but so many books and reviews insist for using bare copper wire, or varnish insulated one.
PVC insulation gives much better mechanical protection at places where wires must be attached or bent.
I just finished a 3 el. cubical quad made of solid copper PVC insulated, supported by 8 fiberglass fishing poles and polyester guying. Up to now, 10 and 15 meters bands installed and fine DX results ; the poles lenght is OK for next 20 meters wiring. Very light and flexible structure, 12 m up on an air-lifted mast. The PVC insulation is usefull for no-sliding, no-harmfull bindings with 3mm polyester guys. It would be much more critical with bare copper or even copperweld.

And as you both say, HF absorption by the dielectric is probably negligible.

Hi Randy ,

In your case since your on the ground floor I would say # 6.. other--- Mag Loop antenna.. the MFJ one is very easy to tune and provides fairly good results close to the ground. They are remotely tunable from about 10MHZ to 30 Mhz. For 40 , 80, and 160 I'd go dual hamsticks made up as a dipole for each band of interest.. But the loop will do well on the upper bands.

hope this helps ,

>r a total loss of ~2.3 dB, which is a
>long way from 90%.

Wes is quite right; although old coax can be lossy, in general it is very difficult to find a (long) piece with high insertion loss at 160M(or 80M).

Few working those lower bands are running ladder line.

Your problem is NOT coax; if it was, then even the sky noise would be attenuated. You have a LAUNCH ANGLE problem;-)

Still curious about my query on your DX window results...agin: do you hear folks near you working DX and you can't hear them?

Source record: 135878

Your antenna is mostly a horizontally polarized radiator, and the launch angle is at or near the zenith.

I would let the coax radiate:if the line isolator is removable, remove it at the feedpoint. Now connect it to a length of good coax corresponding to the vertical height. Connect the line isolator at the base of this coax section, just above --but not connected to--ground.Connect the top of this coax section directly to the apex. DO NOT CHOKE THE COAX IN ANY WAY above the line isolator position.

This is now a vertically radiating dipole(VRD), sometimes called a 'controlled feeder radiator' (CFR). It will be elliptically polarized, with a dominant vertical component.

You will be working loads of DX with this arrangement.

>I don't know how you "verified" 60:1 but I doubt that it's anywhere near there.

First, it appears that I misspoke myself. I looked at my written test results and SWR (without tuner) at the radio at the ends of the bands (nonresonant) averaged around 10.0 -- using a Radio Shack digital SWR meter. At one frequency, where SWR was 12.0 at the radio, I used the same meter on the other end of the feedline, around 8 ft from the feedpoint, and it read 60.0 -- which was predicted here BTW.

Folks here suggested a switch to ladderline because of the high SWR away from resonance. A QST article confirms that this is a good solution. Can you please amplify why my MFJ-986 won't be able to tune my antenna if fed with ladderline? It has no problem bringing the SWR=12.0 down to 1.0.

I am not sure what you mean. Do you mean, Can I hear folks working DX
but they can't hear me? Or something else?

If the former, I have heard folks working DX on 80 and 160, but have
not had an opportunity to call CQ to the participants (because they
were long ragchews). I will try that again.

Ohmmeter shows an open circuit between the center conductor and the
sheathing -- at the radio. So I do not have a short.

If I had a defective solder job at a connector, I would also be having
problems on the 10-20-40 bands, but I am not. I have good DX on those
bands.

It's a parallel dipole that also has traps on one wire. They call them "ISO RES" thingies, and make a big deal about them not having capacitors, but they are really just traps with lots of L and very little C. The C is just the distributed capacitance of the coils.

They have so much L that on 160 they load the 100 feet of wire to 160 meter resonance.
>
>Feedline is 100 ft. of RG-8X

That's decent stuff, and unless you have an open or short the losses on 80 meters will be low up to an SWR of 5 or 6 to 1

>Matching is done with an MFJ-986 at the radio.

I don;t know that tuner. Some tuners are better than others at matching various loads.

>Center is at 40 ft. Ends are at 20 ft. Ground slopes down 10% over
>the length of the antenna. As a result, one leg is almost horizontal
>and the other approximately 45 degrees below horizontal.

I've used lower antennas (homemade trap inverted Vees) that have done a lot better.

In another post you mention Teflon coax around a toroid. at the feedpoint, too.

Here's what I'd do. You have to lower the antenna to do most of this. :

1) Get rid of of the Teflon coax/balun thing. You don't need it. It may be the source of your troubles.

2) Check the feedline for shorts or opens.

3) Check that the entire antenna is assembled according to instructions.

4) Try a different tuner, or even try the antenna without the tuner on a frequency where the SWR is 2:1 or less.

Changing to ladderline is a last resort, and negates the need for the Alpha-Delta.

This is problematic because my shack is high up, only a few feet below
the feedpoint. My current choke is now at the feedpoint. What if I
inserted a length of coax between the feedpoint and the choke? One
leg would go down (up to 40 ft) and the other leg would go back up. I
could leave them close together or some distance apart (like a narrow
"U"). Would this serve the same purpose, or would they cancel out? If
they would cancel out, could I use coax down and something else up
that wouldn't cancel?

This would be an interesting experiment. Would it hurt me on
10-20-40?

I should mention that there is a vertical grounded flue around 30 ft
long around 3 ft from the feedpoint. Modeling showed it had minimal
effect on the dipole's performance. However, it might have a much
greater effect on a vertical antenna 3 ft away.

Well, if you can't break your lease and seek higher ground... :-)

If you can find a telescoping fiberglas pole of some sort, that would enable you to hoist, from your balcony, a 1/4-wave vertical wire for the band of your choice. Connect the wire to the center conductor of your coax. Attach a 1/4-wave counterpoise wire to the braid of your coax, and throw the wire across your apartment floor. This will give you a homebrew 1/4-wave ground plane antenna of sorts. Could work. Experment.

>. . .

It'd be worth a try, but I think that a lot of people running that kind of power are using ferrite beads strung along the outside of the coax (a W2DU balun). Type 43 cores are probably most often used for this. The advantages of this approach are simplicity, broad bandwidth (like a ferrite toroid), the ability to work easily with large coax, and relatively high power handling ability. The disadvantages are cost and weight. If you have N beads each with impedance Z, you get N*Z total impedance. With a toroid core you get T^2*Z where T is the number of turns. So it takes quite a few beads.

There's been a lot of discussion about this on the newsgroup, but a lot of it has been with some lack of understanding. What counts is the impedance seen along the shield toward ground, and the relationship between this and the feedpoint impedance isn't entirely clear. So I'm not sure anyone can really give a good general answer to this. Some experiments and measurements are in order -- maybe you'll be the one to make them.

> Assume that the swr at the feedpoint is 6:1 and that it's resistive on
> one band or another. The feedpoint impedance could be either 8+jï¿½ or
> 300+jï¿½. The proper balun under these conditions should be a 6:1 unit
> connected one way or the other.

I'd personally prefer to make separate transformer and balun, just because it would be easier for me to optimize both. The balun's job is

different from the impedance matching problem, so I'd rather handle each individually.

> The average ham goes out and pops the usual $40 for one of the usual

Depends. Depends on the antenna, the band, and the balun. There's no single answer.

> Seems to me it gets even worse when "they" use a 4:1 balun to feed an
> end-fed wire.

Good lord, yes. Yuck.

> When cometh the point when one simply sez to hell with this
> transformer stuff, just kill the circulating currents with a coil or
> beads and take the coax losses?

It's up to you. You pays your money and you makes your choice.

> Copperweld oughta be outlawed.

I disagree. It's great stuff for a multitude of purposes. The only time it'll cause electrical problems at HF and above is if the wire is teeny tiny. And in RG-174 it is.

> I'm not shooting for "microlight" antennas, I like the idea of using
> 174 for winding compact baluns but I'd use 8X for the run from the
> balun to the ATU. Any hints on the minimum allowable coiling diameter
> for 174?

No. Check with some cable manufacturers' web sites. By the way, RG-8X is considerably heavier than RG-58 and measurements I made of some RG-8X at Dayton showed that the difference in loss for 50-100 feet between it and RG-58 up to 15 meters was pretty small. I don't have the numbers in front of me, but it was a poor trade when I had to carry the cable. I use RG-58 and RG-174 (type) cable for backpacking portable operation.

> Speaking of bridges: Where/how can a ham come up with a half-decent HF
> impedance bridge for antenna work without having to send HP or GR
> $5,000 -8,000?

Get an MFJ Antenna Analyzer. It won't give you the sign of the reactance, and it's not a precision instrument, but it's a whole lot

better than nothing. There are two other solutions. One is to get a GR bridge surplus or on ebay. The other is to roll your own. There are some methods in _Solid State Design for the Radio Amateur_ that work quite well. I used a homebrew resistor bridge with calibrated series X circuit (just a calibrated series LC with variable C) for each band, for many years before I acquired a GR.

Like the picture in the Handbook. I've had a hell of a time describing this for some reason. I must be the only person in the world that winds up rope or extension cords like that, since "like a coil of rope" or "like an extension cord" always brings a bunch of questions like this.

Yes, I tend to agree with the fact that it would not make a good elevated antenna. Since I have a large roll of it and its not really good for use as coax feedline for me, does anyone have any good links for "on-the-ground" antennas for longwave reception? It would be fairly stealthy and I could just unroll it across an unused piece of the property.

Thanks for the help!

>Alpha-Delta.

Could you elaborate on this please? Do you mean that I could just use
a 100 ft long dipole (or whatever I could fit) and just tune that on
160-10 (because high SWR wouldn't matter)? Would it radiate as well
as my multi-wire dipole on 10 and 20 where it has separate wires? Or
do you mean that the 40-80-160 wire with the coils would be
unnecessary and a simple 50' wire would do the job just as well?

> >attention to your antennas ?
>
> Do you really want the kind of attention Cohen gets?

Going by the old adage all types of publicity is good publicity.
Fractal antenna designs made the Arrl book so it can be seen as
a worthy antenna. No sarcastic notes to the Arrl about the legitimacy
of it's placement, it is fully recognised by the Arrl.
Same with Hately, he was recognised all over the World with contracts.
Yet both of these antennas were not recognised by this group tho they
were accepted in the real world by solid actions, building e.t.c.
Now I am not saying that the amateur fraternity is not up to par with
respect to the professional world but it would seem that their
judgments are not reflected by the professional world. Why were the
views so different?
What was it that this group failed to recognise or overlooked that the
pro's
thought worthy of investigation ? Both got bad publicity that
stretched over years and both designers reaped the benefits. As far as
I am concerned
Chip deserved all the aclaim that he received by being in 'the book',
and he is still held in high repute in the academin world and still
has tenure.
So with the Unwin antenna are we following the old adage that the
'second or third liar doesn't stand a chance, presuming that I am
being judged as a liar
or I am insane?
Why did not anyone say that the antenna was a complete washout
because...
as they did with the above antennas to allow outsiders to make their
own judgement? Why were the models created behing the scenes by what
was said
were competant modelers and not shared in the same manner that the

Unwin design
were shared with all? If the sharing of those means 'bad publicity',
then bring on the crowd. Surely the CIA isn't involved with this, the
english are allies,
or is this also not accepted by this group? I don,t want to be like an
artist
whose efforts are only recognised after death, what is holding this
group back?
Publicity even if bad but structered has it's good side.

3850. Re: Modeling coax attached to an antenna in EZNEC

Newsgroup: rec.radio.amateur.antenna
Date: 2002-08-25 14:59:13 UTC
From: Bibby <bibby@attbi.com>
Message-ID: <5h6a9.239971$UU1.39133@sccrnsc03>
Source record: 135891

Roy, I read your response to my response with interest. I am surprised, and disappointed, that others haven't offered an opinion.

Regarding your own comments. I agree with your comments about modeling monopoles. The only reason for introducing it, and mentioning the infinite ground-plane was to show how the frill model came to be applied to dipoles.

Re-reading Doug's original inquiry, I realize that I jumped to a specific case - a dipole - when his question was more generally stated.

Nevertheless, you made a comment that I think needs to be responded to. You say that 'the feed system has nothing to do with the antenna's gain or pattern, and these are the primary things antenna programs are intended to calculate. The calculated antenna feedpoint impedance can be transformed to a value of your choice without any impact on the antenna performance at all, except for whatever loss the transforming network has." What antenna programs are you talking about?

Antenna impedance of dipoles and dipole arrays is also of great interest and importance. In fact, I would say that gain/pattern are subjects that most amateurs only contemplate/dream about as few have the tools to measure them properly. By contrast, impedance matching is something that most amateurs can, and do, do - using their VSWR meters, etc. As you say, the antenna feedpoint impedance can be transformed into whatever you want it to be - but where/how you do it can have a significant effect on the radiation pattern. If the antenna is fed with balance line, led away at right-angles to the antenna and the matching unit is out of the near-field of the antenna then you are correct. However, if the matching is done right up at the antenna feed-point, then the matching system is in, and contributes to, the near-field of the antenna and cannot be ignored. Because the matching unit is in the near-field, it will effect the performance in the far-field (gain/pattern). This is the thought that I was most concerned with in my previous response. It is a very difficult problem from a modeling point of view and so, more often than not, it is ignored. The difficulty in modeling this problem, accurately, is that it would take considerable computer resources to accomplish. But today, we have those resources. So far however, few, if any, programs exist that attempt to do this, never mind do it well.

Art,

If it's simply attention you want, then Cohen, Hately, and your average two year old are good models to emulate. But is that what you want?

You've already succeeded in getting quite a good deal of attention directed toward your antenna, very likely as much as Cohen has gotten directed toward fractal antennas on this newsgroup. (Although you still have a long way to go to catch up with Hately.) But what you really want, I believe, is for your antenna to be accepted and embraced as an important development. While you can get attention by acting in a bizarre and threatening manner or by making outrageous claims, I'm afraid it won't help you convince people that your antenna is great any more than Cohen's behavior has helped him convince people that fractal antennas are. In fact, most people would agree that it's counterproductive.

To convince people that you have a great antenna, the first thing you need is to have a great antenna. And the question seemingly still out to the jury is: Do you?

While I'm not concerned with portability, my balun is exactly that. I found some surplus type 43 (determined by measurement) "sleeve" cores, 1 inch long with a hole diameter just big enough to pass RG-142 through. I have about a dozen of these on the coax, inside an enclosure made from PVC water pipe that it is used for the center insulator of my dipole.

I run full power on 80 meters and haven't cooked anything, although I confess I have not tried to measure any heating. Afterall, it's sealed up and 40 feet in the air, (which should be 104 degrees today) so it's hard to reach <g>.

I may not have communicated well. I see that you might have read this to say that you could tranform impedances with the antenna programs. That's not what I meant to say, and I don't know of any antenna program you can directly do the transformation with, unless you want to deal with NEC networks or do transformations strictly with transmission lines. But the transformations and network design are easily done with programs like WinSMITH.

> Antenna impedance of dipoles and dipole arrays is also of great interest and

All common antenna programs will tell you the feedpoint impedance of the modeled antenna.

> do it well.

That's a really interesting statement. For a matching network to actually radiate enough to compete with the antenna is something that's

never occurred to me. It would require extraordinary currents in the matching network as well as components that are extraordinarily large. The only case where I've seen this is in mobile whip loading coils. I seriously doubt that it's a measurable phenomenon in nearly any common application. There is software capable of doing the sort of complex field analysis you mention. It's in the $20k - $50k and up category. Hardly worth while for someone to write or use a program like this to model an effect that's not likely to be noticeable in the overall radiation pattern. If it really is important to you, though, such programs are available. If you can come up with one you can sell for a hundred pounds, I'm sure you'll have lots of customers.

I'll stand by my statement that matching network has no effect on the antenna pattern or gain (except, of course, the ability to reduce the efficiency due to loss).

In addition to the low cost handheld thingies by MFJ and AEA, look for a surplus Boonton RX meter. I have two of these. They're big and still have vacuum tubes in them, but they can be very accurate, although slow to use.

Another possibility is to find an HP vector voltmeter. These cannot be used directly to measure impedance as they do not have a built in signal source but with the addition of directional couplers or homemade bridges you can make complex impedance measurements.

The downside to these is the total lack of repair parts and the necessity to know how to twist knobs and interpret results.

>...he is still held in high repute in the academin world...<

You must have missed Chip's recent post announcing "retirement" from academia.

>...and still has tenure.<

To my knowledge, Chip never had tenure. Not that that's a strike against him (there's not much incentive for Universities to hand out tenure these days). In a system where poorly-paid foreign grad assistants mumbling unintelligible english do much of the undergrad teaching, it sorta makes you wonder where that 30K-per-year tuition check really goes!

Art, I think the best way to gain credibility is to present your work openly and challenge people to take their best shot at it. You'll either walk away with a lot to think about--or with confidence that you actually got it right. Leave the beyots to the mead hall.

>Chip deserved all the aclaim that he received by being in 'the book',
>and he is still held in high repute in the academin world and still
>has tenure.

I do not know which 'ARRL book' you refer to, and I have retired as an academician; I have so noted it here a few weeks back.

I will confirm that fractal element antennas enjoy commercial success, however they are not being marketed to the radio amateur community and I see no reason to expand upon this here.

Although I appreciate your well wishes, you have made many statements which are not factually accurate in recent weeks, and I request, again, that you cease from doing so.

I am not selling any fractal antennas on this NG, nor have I done so. The thread is a bogus one--if you assume I have any connection with 'fractena@yahoo.com', which I do not.

Your question seems to tie in with notions of how disruptive technologies get accepted; although a topic I have experience in, I fear it is beyond the interests of this NG. I am sorry I cannot discuss it, other than to say that history provides many valuable guides, and human nature never changes:-)

Don't be so down on yourself: Enjoy your accomplishments Art.

Hello all,
I just bought an AR-10 at a local flea market and it didn't come with a
Coaxial Tuning Stub. I have the directions for the antenna and it says
that it 16 5/8 inches.
Two questions:
1) Is this 50 ohm coax?
2) Is the stub shorted?
Thank you in advance for your help.

On Sun, 25 Aug 2002 14:59:13 GMT, "Bibby" <bibby@attbi.com> wrote:

|Roy, I read your response to my response with interest. I am surprised,
|and disappointed, that others haven't offered an opinion.

That's because when Roy answers you, that's the best opinion you're going to get
and the rest of us (present company excepted, of course <g>) keep quiet.
|
|Regarding your own comments. I agree with your comments about modeling
|monopoles. The only reason for introducing it, and mentioning the infinite
|ground-plane was to show how the frill model came to be applied to dipoles.
|
|Re-reading Doug's original inquiry, I realize that I jumped to a specific
|case - a dipole - when his question was more generally stated.
|
|Nevertheless, you made a comment that I think needs to be responded to. You
|say that 'the feed system has nothing to do with the antenna's gain or
|pattern, and these are the primary things antenna programs are intended to
|calculate. The calculated antenna feedpoint impedance can be transformed
|to a value of your choice without any impact on the antenna performance at
|all, except for whatever loss the transforming network has." What antenna
|programs are you talking about?

Roy is too modest to recommend EZNEC one that he sells. However, I'm not, I
highly recommend it. There are others both freeware (MultiNEC, MMANA) and
commercial from Nittany Scientific, et.al.
|
|Antenna impedance of dipoles and dipole arrays is also of great interest and
|importance. In fact, I would say that gain/pattern are subjects that most
|amateurs only contemplate/dream about as few have the tools to measure them
|properly. By contrast, impedance matching is something that most amateurs
|can, and do, do - using their VSWR meters, etc. As you say, the antenna
|feedpoint impedance can be transformed into whatever you want it to be - but
|where/how you do it can have a significant effect on the radiation pattern.
|If the antenna is fed with balance line, led away at right-angles to the
|antenna and the matching unit is out of the near-field of the antenna then
|you are correct. However, if the matching is done right up at the antenna
|feed-point, then the matching system is in, and contributes to, the
|near-field of the antenna and cannot be ignored. Because the matching unit
|is in the near-field, it will effect the performance in the far-field
|(gain/pattern).

Why do you think this is necessarily so? Look at:

http://users.triconet.org/wesandlinda/YagiFeed-1a.jpg

and

http://users.triconet.org/wesandlinda/YagiFeed-2a.jpg

(This is a "top" view of the antenna with the tower folded over.)

Here impedance matching and a balanced-to-unbalanced transform are performed in one structure located right at the feedpoint. Are you suggesting that there is significant radiation occurring in this matching structure? It is after all a balanced line normal to the dipole.

I should add that this antenna, a 3-element Yagi, was designed using EZNEC for the electrical part (gain, F/B, Z) and spreadsheets from "Physical Design of Yagi Antennas" to calculate the mechanical properties and electrical equivalents of the element clamps, etc. I separately calculated the impedance of the stub, a balanced line over a ground plane (the boom) and putting it all together, it came out almost *exactly* as predicted. It took two very minor adjustments of the stub shorting bar and driven element length to achieve the desired match and the measured SWR bandwidth is *remarkably* close to predictions. This stuff works.

|This is the thought that I was most concerned with in my
|previous response. It is a very difficult problem from a modeling point of
|view and so, more often than not, it is ignored. The difficulty in
|modeling this problem, accurately, is that it would take considerable
|computer resources to accomplish. But today, we have those resources. So
|far however, few, if any, programs exist that attempt to do this, never mind
|do it well.

Send a fist full of thousand dollar bills to:

Ken, KC2JDY wrote:
"I should mention that there is a vertical grounded flue around 30 ft long around 3 ft from the feedpoint."

The effective height of Ken`s inverted V dipole is very low. Now Ken reveals his shack height is around that of his dipole and contains a variety of grounded items including a flue pipe.

Several respondents say it`s too low. Others say they work DX with dummy load leads. It is affected by location.

Ken`s antenna is too low.

Edition 19 of the ARRL Antenna Book shows on page 3-11 patterns of a full-size, non-drooping, dipole with real, not imagined, ground clearances. Propagation gets good at 1/2-wavelength height.

Compare the groundplane vertical antenna patterns on page 3-13. A groundplane up only 1/8-wavelength has good low-angle radiation. The effects of good ground conductivity are apparent in Fig 16-A.

On page 3-14, the Antenna Book says:
"Real ground, with finite conductivity and less-than-perfect dielectric constant, can severely curtail the low-angle radiation at which verticals are supposed to excel."

"---Practical installations for 160 and 80 meters rarely allow amateurs to put up a horizontal antenna high enough to radiate effectively at low elevation angles. After all, a halfwave on 1.8 MHz is 273 feet high---."

Hi Art,

Liar? Insane? No - pathetic (given your repeated preference to embrace these negative qualities that no one but you brought to the table). I don't buy how you died (Hately, forgive them....) and rose to save us from our sins of overlooking vastly superior designs. We are tired of asking for specifics of your design and being offered views of your stigmata.

If you truly aspire to the heights of Fraudtenna coverage you need only start a few illegal lotteries, name an innocent Ham brother as a vicious serial murderer, have your best design trounced 6 times over in open competition, and begin threatening everyone here with suits over fantasized claims of imagined patent pending protection. One clear market advantage you might also emulate is to offer cyanide capsules to each customer to insure your design is not duplicated surreptitiously (also prevents those embarrassing questions of: how much more gain?). Is this really your idea of the magnanimity of a noble mission?

You wrap yourself in this mantle of the fractal, and get diss'ed for doing so in a manner that mocks your trust:
>>your facts are incorrect, and
>>I will not attempt to understand why they are even posed in this antenna forum.
Pathetic is how you can absorb that abuse with bonhomie and then rail against those who worked hard in your behalf.

Richard,

This has already been said. Kindly see my previous posts on this.

My suggestion was to lower the line isolator to just above the ground and let
the coax radiate as a vertical radiator.

BINGO

Hi Ken,

Follow the newsgroup for a couple of weeks and you will eventually
read a fair amount of correspondence to this matter.

However, back to the problem at hand. You've been advised to test the
cable, but so far not to a method that would definitely reveal a
problem.

Put a dummy load and power meter at the far end of cable, key down,
read power, key up, move meter to rig end of cable, key down, read
power, key up.

Compute the ratio of the two powers. Take the ratio's log and
multiply by 10. Multiply that product by 100, then divide by the
length in feet of your cable.

The last operation will yield your cable loss in dB/100feet, a
standard specification for cables such that I can offer some
representative values at 10MHz:
RG 58 1.5dB
RG11 0.7dB
7/8ths 0.1dB
Loss is linear to cable length, so measurement is not as critical as
compared to issues of resonance. If there is anything wrong with your
system up to the antenna, this will reveal it in a heartbeat.

If you decide to go twin line, the same mission serves as a sanity
check of your connections and transformations.

Source record: 135912

Hi!

I have a (new) used Bird wattmeter with a couple of medium power slugs.One is for 400-2500 Megs and the other is 50- (I think)400 Megs.

I noticed that I could reasonably use the latter at 28 MHz to a fairly constant factor : in other words, the value would read wrong, but if I scale by a constant I can get the right power.

My question: how linear are these slugs at the edge of their passbands?(Is the value at 52 MHz within, say 2% precision?)

If I use a 50-400 slug at 28 MHz, will the relative scaling still hold as I decrease power?

Think of it this way--its always preferable to have the right slug. But can you use what you got if stuck?

Hi Bob,

From the way you ask the question it seems you already anticipate the
snake-in-the-grass antenna. I was about to respond to your other
query with a suggestion of a Beverage design.

Elevate 2,3, or more wavelengths of your cable a dozen feet and listen
on the shield. If you cannot elevate it, then lay it out and listen
on the center conductor. The specifics as to if the far end is
terminated, opened, or shorted escapes me... that should resolve with
simple testing. You should have a good local ground screen (8 radials
out a couple dozen feet - use cable shield here too, along the ground;
no need to strip it, insulated will work fine - probably better).

Richard,
Terminate it in a resistor of the same value as the
coax's characteristic impedance (75 ohms). Will it be
a great antenna? Nope, but it will work. Needs to be
at least 1 wave length long, and is a 'single band' thing.

Thank you for something I understand. To do this right, I have to get
to my feedpoint, which requires some effort. Some time this week I
will do it.

So -- anticipating things a bit -- if I find loss per 100 ft. of say
under 1 dB for my whole RG-8X feedline plus current balun across the
whole HF spectrum, then my feedline is probably OK.

I would still have to decide whether replacing the coax with ladder
line will help or will just overload my tuner.

To test a ladder line feedline with a dummy load having an SO-239
connector, do I need a fancy balun? Or just connect the ladder line
leads the sheathing and center conductor the cable out of a PL-259?

The problem is pattern not ladder.

Either:

1) Change the height;
2) Make the antenna a vertical radiator by changing the line isolator position
and let the coax radiate.

If I might iterject here, is my 40 ft high feedpoint to low because it
should be 273 ft? Or because it should be 50 ft.?

The former I can't do anything to remedy. The latter I might be able
to address, with some effort.

3881. Horizontal Loop Question

Newsgroup: rec.radio.amateur.antenna
Date: 2002-08-25 19:49:04 UTC
From: karl <wb0vzz@email.msn.com>
Message-ID: <3d69334a$1@news.sihope.com>
Source record: 135820

Dear members of the group,

My current antenna is as follows:

A horizontal loop with a circumference of about 141 feet (1005/7.15 = 104.6 feet). It's 8 feet above the roof of a four story apartment building. It's fed via an autotuner with 450 ohm ladderline. It tunes well on 40/20/17/20 which are my bands of interest. The SWR is typically about 1.2 to 1.6.

I am considering increasing the size of the loop. The available area on the roof would allow for a loop of about 45 feet by 75 feet. That would increase the circumference to 240 feet. This would figure to a frequency of 4.2 MHz. The shape would not be a square, obviously, but maybe it's too rectangular.

Would this increase to a "random" size offer any benefits, or would I experience a degradation in performance?

Yes, there is the popular school of thought of "try it and see." Please forgive my laziness for asking for input from the group as to opinions and/or someone's quick modeling output. If there is a clear advantage/disadvantage to trying it -- well, to the roof I go!

This experimentation process involves construction, usage for a few weeks to allow for variations in band conditions, decision, and possibly repeating the process. The current antenna is constructed in a semi-stealth fashion using enameled wire, fishline, cable ties for insulators, etc. Once a final design is determined, I'm going to build it with more stout materials; 14 AWG flexweave, conventional insulators, sturdier supports, and such. I live in Minnesota, and the winters are long and hard. The final version must withstand the winter (fingers crossed).

Thanks in advance to the replies.

73, Karl K0TBT

Even a short piece of radiating coax (that is the 40 ft) will give you substantial improvements on 80 and 160 for DX.

Is it really not possible to insert a 40 ft section of coax at the feedpoint down to the line isolator?

I will be the first to apologize for giving the wrong answer if this 5 minute experiment failed...

Okay, I give up. I can't hit a moving target.

First it was: "At the ends of the low bands, however, untuned SWR goes to around 6.0 at the radio."

Then it was: "At one frequency, where SWR was 12.0 at the radio,..."

The "end of the band" in the example below is 3.6 MHz and the topic spans two (or is it more) threads.

I don't know what "calculator" was used below but you cannot predict an exact line loss based only upon the input SWR.

Source record: 135826

If I restrict my remarks to "freely available", "available at low cost", "public domain", etc., then I think that we are all in violent agreement.

Wes, your design looks very interesting. Were you able to measure the gain/pattern? If so, how and what were the results?

Roy, my thinking on antennas is often biased towards thinking in the vhf/uhf application range. There, as you know, much of the conventional antenna theory is "first order" at best due to the failure of various assumptions, particularly that radii are less than 0.01 wavelengths. Consequently, I spend considerable time and energy chasing "second order" effects. Modeling an 'in situ' matching network may be one of those things.

Thanks to Roy and Wes for their comments.

Malcolm, W1/GW3NJY

P.S. Roy did you really mean pounds or euros?!

By "line isolator" I assume you mean a common mode choke, or "current balun". This device doesn't abruptly stop current at one point while allowing radiation from all points above it. Depending on its position in wavelengths relative to the antenna and the length and orientation of the line above and below the antenna, its effect can be to reduce current dramatically on the entire feedline or to simply redistribute current. So, although it might (or might not) be advantageous to have a radiating feedline, putting a balun or "line isolator" at the bottom of the feedline doesn't assure line radiation above that point.

Hi Ken,

You will need either a Dummy Load equal to the characteristic Z of the
feed line (50/75/90/200/300/600)

OR

You will need a lossless (or low loss) impedance transformer to shift
between that same Z & 50 Ohm Dummy Load.

It is not difficult to obtain useful transformers, and this test will
separate out the best of them.

Hi Jake.

I have 3 other suggestions. I've been writing basic technical notes
for military radio operators and hams like myself. Yes the arrl antenna
handbook is the bible but there is also:

Cubical Quad antennas, William Orr and Stuart Cowan (RAC)
Practical Wire Antennas, John D Heys G3BDQ (RSGB)(great for novice hams)

and of course the superb ...

Antennas and Techniques for LOW-BAND DXing, John Delvoldere,ON4UN (ARRL)

Well there's my contribution ...
Francois.

When you impersonate someone, and use the internet to hide your identity, and don't reply to queries via e-mail, its not surprising that folks feel duped and taken advantage of.

I suspect that you will find out my sense of injury on the matter--which continues by others off this NG.

If you have any sense of common decency you will offer me and others here the respect of not impersonating others.

Hi Karl..
Your 240ft loop,fed with about 40ft of 450Ohm ladderline will
give you a low SWR on 80m.(no tuner required, but a choke balun would be
helpful at the shack end of the ladderline). If you add a 1/4 w/l of coax
for 40m to the ladderline, it will also resonate on 40m. However, if your
ATU is of decent quality, I'd expect the loop to be excellent on all bands
80 through 10m, and it would work reasonably OK on 160m too. With the
dimensions that you propose, it is a W9LX on 80m. If you opened the loop at
the opposite side to the feed, you'd have a bent 160m dipole..
'been there...done that... have the T shirt.. Loops are great...but
I'm biased..!!

Not familiar with those mixes. If you're using a Fair-Rite product, use 43 or 61 mix--depending on which end of the UHF spectrum you're dealing with (43 toward the low end and 61 near the higher end). You can mix them, too.

Don't know what kind of slugs you have but the ones I have seen in
that range go from 400 -
1000 mhz.
The 50 mhz one goes from 50 - 125 mhz.

But yes they will work outside those ranges quite well. The higher
power the slug the broader
the bandwidth it is. For example a (500C), 500 watt 100-250 mhz slug
looks nearly flat from
20 mhz to 1000 mhz. It's response is down about 1 db at each end.

Compared to a (100C), 100 watt 100-250mhz slug which is down about 3
db at 20 mhz and
down about 5 db at 1000 mhz.

A (10C), 10 watt 100-250 mhz slug is down about 9 db at 20 mhz and
down about 8 db at
1000 mhz.

From the chart that I have it looks like the 100C starts to fall off
at around 50 mhz. At 30 mhz it
looks like it is down about 1.5 db and down 3 db at 20 mhz. On the
high end it starts to fall off

at about 400 mhz.

I don't have a chart for the 50 mhz slug but it's response will
probably be similar as a percent of
frequency difference.

The linearity should be the same if in band or out of band with the
slug.

At best the Bird accuracy is + - 5% of FULL scale with the proper
frequency range slug.
Remember with a 100 watt slug that means the accuracy is + - 5 watts
on any part of the scale.
So if you are measuring 25 watts with a 100 watt slug the error can be
as much as + - 20%!

>down to the line isolator?

No, it is not impossible. But then I would need a 40 ft section of
coax to get back up because near the feedpoint is where the coax comes
into my house for a 70 ft run. I would have to make a different path
through my house to get to the shack if I don't come back up. The
down and up won't work, I fear.

For an experiment, I would need around 200 ft of coax to take the
down-around-up route.

In answer to your previous question about the DX window, I hear lots
of phone DX in the 80M DX window, but am not authorized to TX there.
I hear nothing in the 160M DX window.

Ken, KC2JDY wrote:
"---I would also be having problems on 10-20-40 bands, but I am not."

That`s evidence the coax is good. The problem
as Chip and others have said is a low horizontally polarized antenna.
The inverted V antenna would normally have some vertically polarized
energy.

Ken`s V antenna has two problems. First, the effective height is much
less than 30 or 40 feet due to the clutter of grounded pipes and wires
in the house next to it. Second, is a grounded vertical flue pipe next
to the feedpoint. Reradiated energy from the flue pipe is about
180-degrees out of phase with any energy which might be radiated by the
coax. That`s just fine for bands where the dipole is effective. For 80
and 160 meters where the dipole is far too low to be effective, the flue
pipe is probably a killer for vertically polarized radiation.

To disarm the flue pipe, a parallel wire connected at the top of the
flue pipe but otherwise insulated from it, and not grounded at the
bottom as the flue pipe is, may help. Or, shunt-feed the flue pipe and
try it as a radiator on 80 and 160 meters.

Ken`s antenna arrangement has proved to be bad on the lowest bands. His
coax has proved to be good by its performance on higher bands.

The ground mounted vertically polarized antenna must have a good ground
to perform well, especially because it will be too short. But the
vertical can have useful radiation. The antenna Ken has now does not.

Best regards, Richard Harrison, KB5WZI

Very little evidence to support that claim! Try the V legs as radials and erect a resonant loaded vertical whip over the feedpoint. See the improvement that will make. Lengthen and add radials for more improvement.

Best regards, Richard Harrison, KB5WZI

Yes.

Your antenna is not vertically polarized or, if it is, there is some phase cancellation which is killing low angle stuff. Richard has a nice discussion on this I note.

Choke that sucker--just not at the feed.

|Wes, your design looks very interesting. Were you able to measure the
|gain/pattern?

In a word, no.

I've done a fair amount of work in anechoic chambers doing gain, pattern and axial ratio measurements at frequencies up to 35 GHz. I have also done some open field stuff at 1.5 GHz, so I know better than to try and do any significant measurements at 14 MHz with amateur type equipment.

I honestly believe that the models are accurate and predict the performance better than I would be able to measure it, therefore, I am happy.

It will be easier to get it to load on 75/80 and 160. Also, you may see it become a bit directional on the higher frequencies. Experiment away and have fun! I used a loop around my house when I lived in Eden Prairie - no problems with the Minnesota winters!

Good luck and 73,

Chip, N1IR wrote:
"How linear are these slugs at the edge of their passbands?"

Standard Bird elements come in the following frequency bands (MHz):
2-30, 25-60, 50-125, 100-250, 200-500, and 400-1000. There are many more slugs for low power, high power, higher frequencies, etc.

Accuracy specified is 5% of full scale

Low power and low frequency require tighter coupling. Accuracy is probably better on loosly coupled slugs, or over a smaller range on more tightly coupled slugs. When the distances within a slug become significant in terms of wavelength, accuracy may decline. Again, Bird can just narrow the specified band pass to stay within their specified 5% accuracy.

For greater accuracy two slugs, a high power slug for forward power and a low power slug for reflected power, can improve results.

Bird will probably gladly supply a replacement manual and more, reprints of their "Technical
Series", on request. Secrecy is long gone as some makers of similar products now have slugs which directly interchange with the Bird elements. Most deny the interchangeability, but they usually produce identical results for me. Bird elements usually look better and cost little if any more than the off-breeds. Availability may be better from Bird, too.

Sorry I haven`t checked the deterioration of accuracy at the band edges. More accurately, I don`t know how much better than 5% of full scale the Bird element is at mid-band.

Best regards, Richard Harrison, KB5WZI

Source record: 135851

Karl,
Increasing the size of the loop to somewhere around
240 feet will give you 80 meter capability. It will
also change the characteristics of the antenna on other
bands. 40 meters, since it would be the 2nd harmonic,
isn't going to be as 'good' as what you see now, neither
will 10 meters. The radiation pattern will change on
all bands and it may not be 'pointed' where you want it,
but then again, it might be.
There are a lot of things that affect how well an
antenna works, as I'm sure you know. The only thing that
anyone can tell you for sure is that things will change,
not if it will be for the 'better' than what you have now.
I've been in your situation and was very happy with an
80 meter loop. Compared to a dipole, it worked out 'better'
considering the low height I had available, and I was
interested in 80 meters anyway. It's that same old 'deal',
you won't know how well it will work for you till you try it.
'Doc

I don't know how relevant this is, but I sometimes use kapton tape for insulation in the course of my work. It looks and feels very much like a smooth mylar. I would assume that two surfaces covered with it would easily slide over each other. I caution you, though, that kapton tape is expensive, so I would assume any "bulk" supply of kapton would probably also be.

The solution that I have used for several years now is the AEA/Tempo CIA-HF analyzer. It costs about twice what a 259 does, but it plots R,Z, X, SWR, etc.vs frequency as well as presenting tabular data. I have observed that 98% of the time, the sign of the reactance is correct.

It is an expensive instrument and the microprocessor is quite slow, but it seems to produce consistent results which tend to be accurate.

I have found that the added information obtained from the plotted data far outweights the added cost. Manual searching for data points just allows too many to fall in the crack - at least for me.

I also have a very good GR 916A if anyone is interested in a *real* impedance bridge!

That last sentence may be too sweeping, because the "usability" of any RF insulating material also depends on the dielectric stress it's subjected to - and that's often the hardest part to predict.

For example, you can make excellent chimneys for tubes like the 4CX250 series, 3CX800, 8877 etc. by rolling up a sheet of teflon and securing it with a wrap of mylar parcel tape. Now you might think that a poor dielectric like mylar would be very unlikely to work in this situation: the strip of tape runs straight up-and-down between the anode of the tube and the grounded lid of the case - only about two inches in some VHF stripline amps - and it also has to operate in a stream of hot air. But mylar tape actually works very well in this situation (credit goes to W2GN).

Delrin is another example of a not-very-good RF insulator. In the wrong situation, I've melted Delrin within seconds in a 50W amp for 144MHz. On the other hand, Delrin pillars work just fine as supports for the tank coils of some commercial 1.5kW amps. Same material, different RF situation, different performance.

The tuning capacitor for a small loop is one of the few cases where you can predict the RF voltage and current quite accurately... but more generally, intuition about RF field strengths can be a poor guide.

Hello to All
The South Dallas Amateur radio Operators (SDARO) would like to extend an invitation to all Amateur's in the Dallas area and beyond to meet and discuss new and innovative ideas to better serve the Dallas area community. SDARO has been an active club in the Dallas area for over 20 Years and is considered a brick road of talent to be shared with Everyone, Ham Radio Operators and the General Public alike.
In the past 10 Years Amateur radio has expanded to many new technological aspects and We would like the opportunity to help broaden the horizon's of aspiring Hams in these new modes of operating while giving Them the opportunity to exhibit Their skills and incorporate them as a respected force within SDARO
Some of the projects on the table now are :
Coordination of a Dallas area SDARO club repeater .
Inducting new Members to participate in community events. And to also to establish a Emergency Communication Team to be available in times of disaster.
We would like to see new and old Hams in the Dallas area step up to the challenge of carrying a torch that has burned a brilliant flame for 20 years and be part of the success that is foreseen for the future by Your participation and support.
We welcome You to share Your ideas with Us . And offer to share Our experience with You .
Our meetings are held every 2nd Saturday of each month at a Dallas area library and is open to the public to attend.
For more information regarding location and time for the meeting and Membership , Please contact the President of SDARO, Mr.Fred Ratciff (KK5TN) at (972) 572-0560 or Club Secretary Mr.Jimmie Thompson (KX5S) at (214) 376-3878.
The SDARO is looking forward to meeting YOU and the expectations of Dallas area Amateur Community.
73"

The problem I get up there is the lengths of coax I use are usually smaller than the beads;-); bazooka baluns end up being smaller too!

But thanks for the info.

Something else which is really cool (not totally related)--but decreases measurement headaches: DAMS at

www.diamondeng.net

Don't have one yet but the engs there are very informative and sound like they did it right. We're a Lab Vu house and have something similar; at some point though its easier to buy than to make!

Just a thought.

One more bit of information. I did run EZNEC for my antenna and it
showed that the flue had an insignificant effect on propagation across
all frequencies. My results were confirmed by a seasoned user of that
program.

At this point, I have reliable information that:

The flue has no effect
The flue is hurting

I should switch to ladder line
I shouldn't switch to ladder line

The feedpoint is too low
The feedpoint is OK

I guess I will try some suggestions in the order of difficulty.
-Shut feed the flue or add the outside droopy ungrounded wire.
-Switch to ladder line
-Raise the feedpoint ten feet with a Mast Co. unstayed aluminum mast.

Such programs do a poor job of simulating real environments--unless you like to
view the world's structures with a wire mesh, which I doubt your 'seasoned
user' took the time to do on this problem.

You have plenty of stuff in the near field so there are probably opportunities for currents at places you don't expect.

JUST--LET--THE COAX--RADIATE:-)! Control the coaxial radiation by placing a choke down the bottom. Make lemonades from lemons.

That's it for my advice on this thread. Maybe Richard has a bit more patience than me.

73,

The coaxial length forms a coaxial capacitor- part of the L-C Z transformer-
so the coax is left open. MY redcollection is that it is 50 Ohm solid
dielectric- this is important as the pF/ft is a function of dielctric and
the coaxial impedance-

Ken has received opinions based on his description of the antenna installation.

Coupling between conductors is based on proximity and parallelism. Ken`s flue is vertical, close, and parallel to the vertical component of radiation from his inverted-V. The vertical component of his radiation is the only useful part at 80-160 meters.

For the line feeding an inverted-V, see page 6-3 of the ARRL Antenna Book. Coax is used without any balun or choke to feed the inverted-V. Impedance at resonance is lower than the 75-ohm flat-top dipole. At 80-160 meters, Ken`s inverted-V has a high capacitive reactance because it`s too short. But, the real problem is the antenna is too low to usefully radiate as a horizontal antenna in the lower bands. A short vertical can work which is why Chip suggests using the coax as a radiator. Look up the "Multee" antenna which uses the dipole as a capacity hat on the coax used as the actual radiator on the lowest band.

The feedpoint is not at an OK height for a horizontal antenna at 80-150 meters. You don`t need to model it. You`ve tried it and it doesn`t work. All the textbooks tell you it won`t work. You`ve confirmed what the books say for yourself. Contrary to popular myth, wishing won`t make it so.

Best regards, Richard Harrison, KB5WZI

Has anyone looked into StepIR's new vertical? What kind of ground plane requirements. Pole mounting, etc.

Dan,

That explains it.

The January 2002 CQ had an unfortunate editorial error in that at least
two articles were actually intended to be published on April 1.

The ground theory article and the dipole-buried-in-a-lake article are
complete, total, utter, unadulterated nonsense.

These articles were discussed in this newsgroup about six months ago.

3932. Installing ladder line -- some help from ARRL

Newsgroup: rec.radio.amateur.antenna
Date: 2002-08-26 19:36:44 UTC
From: cprstn54zz@att.net
Message-ID: <3d6a81fa.31857015@news-server.optonline.net>
Source record: 135773

I asked the ARRL Tech Info Service some questions on the nitty gritty
of installing ladder line. The helpful answers are excerpted below:

<<< (1) Can it be stapled to wood studs with steel staples in the
middle insulator?

yes, it can.. no problem.

<<< (2) Mine will run parallel to and 12" away from a galvanized A/C
duct for 40 ft. Should I twist the ladderline? How often?

12" is good and half twist about every 18"

<<< (3) When crossing household wiring at a right angle, how close can
I come to it?

6 - 8 "

<<< (4) Can it pass through (perpendicular) a small opening in a 2
square foot chicken-wire screen?

yes

<<< (5) Can I hook one side of it over a small steel hook used for
strain relief near the feedpoint?

yes

3935. Re: Modeling coax attached to an antenna in EZNEC

Newsgroup: rec.radio.amateur.antenna
Date: 2002-08-26 22:26:18 UTC
From: Douglas Stinson <douglas-stinson@attbi.com>
Message-ID: <eWxa9.284605$sA3.545570@rwcrnsc52.ops.asp.att.net>
Source record: 135776

I've heard 'cautions' about measuring antenna patterns and gain. Is it really as bad as all that? Gain -- which would require an absolute measurement somewhere along the line -- I can understand as being quite difficult.

I tried to measure the pattern of an antenna I built. Most of the things I tried didn't work very well. But I seemed to get pretty reasonable and consistent results when:

(a) I measured the recieved signal strength using the test antenna while my wife transmitted from the other side of a lake. (Received power was determined by the amound of attenuation which needed to be inserted to obtain a constant S-meter reading.) and

(b) I measured received signal strength from a "fox" with the test antenna located on the top of a steeply sloped hill during a transmitter hunt.

Anything I should be "beware" of?

I don't know the configuration of the AR99, but you could elevate it 8-10 ft. and add four quarter wave radials under it. If it's a quarter wave, this would help. If it's a half wave job, probably makes no improvement.

Good Luck,

Bill, W4WNT

3937. ARRL Maryland-DC Section Convention & Hamfest

Newsgroup: rec.radio.amateur.antenna
Date: 2002-08-27 00:03:10 UTC
From: "E. Allen Brown, FALLFEST 2002 Programs Manager" <KZ3AB@ARRL.net>
Message-ID: <3D6AC1BE.DB706AE4@ARRL.net>
Source record: 135778
Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.boatachors,rec.radio.amateur.homebrew

The Foundation for Amateur Radio (F.A.R.) and The Columbia Amateur Radio Association (CARA) have joined forces to create what will become one of the premier Amateur Radio events in the Mid-Atlantic region.

The dates are Saturday, September 7 and Sunday, September 8, 2002 at the Howard County (MD) Fairgrounds west of Baltimore near the intersection of I-70 and MD-32.

See: http://www.fall-fest.com/ for details and directions.

VE Exams (amateur radio tests) will run from 8:00 am - 12:00 n on Sunday, September 8.

Skywarn classes run from 12:00 N - 5:00 pm on Saturday, September 7. See: http://www.fall-fest.com/skywarn.shtml for info on how to register.

Many vendors have reserved space including "Satellite Sam," the "RF Connection," the "Badge Man," "Startek," "Ramsey Electronics," and more.

Seminars will include:

Amateur Microwave Communications with Bill Seabreeze, W3IY
RF Interference Investigation with Mike Martin, K3RFI
AMSAT Satellite Communications with Rick Hambly, W2GPS
Coordinated ARRL Presentation with Tom Abernethy, W3TOM, ARRL MDC SM
Demonstration of the Marconi Detector by Chip Weems, W4PBG
APRS Demonstration by Bob Bruninga, WB4APR
Amateur TV demonstration by Tim Keener, N3VGS

And more!

A special event station will be on the air demonstrating vintage and homebrew equipment (radios that glow in the dark) with that wonderful rich
sound of AM radio from the "old days."

For more info, contact: <info@fall-fest.com>

Alright, so currents are induced on the flue. So what? Given a
high-enough flue, it will be an efficient radiator, a passive element,
and it will radiate somewhere. Does it change his pattern? Sure. Does
it act as an absorber. Nope. There could be a problem if coupling back
into the antenna changes the impedance match, but Ken's SWR numbers
don't appear to be way out of range.

> The vertical component of his radiation
> is the only useful part at 80-160 meters.

Where did you read this? This is absolute nonsense. You're probably
confusing vertical component with a vertically polarized antenna, like
a monopole, which has better gain at low take-off angles than an
inverted Vee.

From what I've read of Ken's messages, he is not trying to get into
Europe or Japan, he's just trying to get further than 30 miles. His
antenna, if working correctly, would do just that. Maybe not thousands
of miles, but at least several hundred. The antenna height is not the
problem.

Looking at the manufacturer's web site for his antenna, the design
uses a coil in each 80-meter arm. Those coils could be the problem.

> For the line feeding an inverted-V, see page 6-3 of the ARRL Antenna

Let me ask you something - and I would like an honest answer. Have you ever actually tried an inverted Vee or a horizontal dipole on the 80-meter band? I have many years of actual experience with horizontal dipoles, day-time and night-time. Have you ever acted as Net Control on an 80-meter net at 6 PM in June? I have. Have you ever made late-morning contacts on 80 meters during Field Day? I have. What's your experience?

Source record: 135780

Amen Bill, I said the same thing. If he can't get over 30 miles the problems are more severe than all the theoretical crap about takeoff angles.

By the way, I HAVE done all the things you listed and have over 200 countries on 75 using the much maligned G5RV.

I know for example Chip is a very competent operator on 10 and have listened to him working DX, I have never heard him on 75.

My example of exceeding the distance loading up a 100 watt lightbulb with a DX-100, in the AM days, was to show him that regardless of takeoff angle, any antenna will let you get several hundred miles.

I would have checked the coax, then the traps. He said the coax was OK and you beat me to the punch on the traps. I would expect a signal to get out even if the traps were open if his tuner kept the transmitter from folding back from high SWR.

3941. Re: What am I emitting on 80M?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-08-27 02:56:39 UTC
From: richardharrison@webtv.net
Message-ID: <10204-3D6AEA67-471@storefull-2395.public.lawson.webtv.net>
Source record: 135783

Bill Klocko, N3WK quoted me:
"The vertical component of this radiation is the only useful part at 80-160 meters."

Bill wrote:
"Where did you read this? This is absolute nonsense."

Just read my previous posts in this thread. I gave page and figure numbers from the 19th edition of the ARRL Antenna book. I`ve read many antenna books and the ARRL book is an echo of what the other books say about low dipoles and short verticals.

Bill also wrote:
"Have you ever tried an inverted Vee or a horizontal dipole in the 80-meter band?"

Never tried an inverted-V in any band because I never had to make such a compromise. The inverted-V is a good compromise for amateur work. ON4UN`s survey of well known DXers shows them to be a favorite transmitting antenna. Almost certainly those used by contest champions bear little resemblance to the antenna discussed in this thread.

I have also never erected a dipole for use in the 80-meter amateur band. That seems not too different to me than the countless horizontal and vertical dipoles I have erected for commercial pursuits at frequencies above and below the 80-meter ham band. I`ve put them up in Europe, North America, and South America. I`ve also erected Curtain Antennas for almost every shortwave broadcasting band, more rhombics than I can count, and numerous dishes, periscopes, and scop antennas in many different microwave systems where I
was the principal designer. I started in mediumwave broadcasting in 1949. I have a BSEE degree thanks to the GI Bill. I`ve installed power frequency equipment too.

This thread is about an antenna that doesn`t work in a couple of bands. I`ve thought hard, and I don`t remember one of my antennas that didn`t work.

Best regards, Richard Harrison, KB5WZI

3942. Waveguide Antenna.

I am looking for sources and or detailed plans / diagrams (dimensions),
design software for a waveguide antenna for 890mhz through 914mhz.

I am also looking for sources and or detailed plans / diagrams (dimensions),
design software for a feedhorn for 935mhz through 959mhz.

Any and all assistance and advice will be welcome.

3943. 2-Meter Co-Linear

I am planning on replacing my old (10 years) antenna. I am planning on making my own Co-linear. The question is;

If I use 3 or 4 sections, will it be worth the extra sections gain wise, then a 2 section.

Thanks in advance

Chuck

Bill Klocko wrote:
"Alright, so currents are induced on a flue. So what?"

A coax with longitudinal (common-mode) current on the exterior of its sheath might be the source of lower-angle radiation, good for a hop in excess of 30 miles were it not for the flue.

RE-radiation from the flue is 180-degrees out of phase. The effect of the pair made from the coax and the flue is much like a pair in a parallel-wire transmission line which leaves the radiation to the horizontal dipole.

In Ken`s case, the horizontal dipole is useless at 80-160 meters. Vertically polarized radiation from the coax would possibly produce some useful lower-angles for longer hops.

Best regards, Richard Harrison, KB5WZI

Waveguide and horns are going to be pretty big at this low a frequency.

You can find detailed instructions for slot antennas at
http://www.ij.net/packrats/Slot_Antenna/slot.html going down to 1.1GHz.

I guess you could scale it easily enough if you can find wave guide
that big.

Horn designs can be found in just about any of the UHF/microwave books by
the ARRL or RSGB.

Fred Hambrecht wrote:
"If he can`t get over 30 miles the problems are more severe than all the theoretical crap about takeoff angles."

The antenna works on 40 meters and higher frequencies.

It produces NVIS at 30 miles on 80 meters.

Low horizontal antennas are cloud warmers.

If Ken had no flue pipe, chances are the high impedance of the too short dipole on 80-160 meters would divert current to the coax exterior where the radiation produced could skip out beyond 30 miles. As it is, radiation is produced but mostly at useless angles.

Best regards, Richard Harrison, KB5WZI

Only Chuck can answer that. It`s a personal decision what something is worth.

There is a 2-section co-linear 2-meter antenna, "The Super-J Maritime Antenna" in the 19th edition of the ARRL Antenna Book on page 16-24 for starters.

Best regards, Richard Harrison, KB5WZI

3949. Re: Linearity of Bird Wattmeter Slugs?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-08-27 05:17:22 UTC
From: "Bob M." <xxxxx@yyyy.zzz>
Message-ID: <CXDa9.110436$Aw4.4759180@bin2.nnrp.aus1.giganews.com>
Source record: 135790

I'm using Coaxial Dynamics elements (www.coaxial.com) with my Bird 43. They work fine and are less expensive than Bird elements. I believe that you can only buy new Bird products directly from Bird these days, however there's always stuff on eBay. NOARD in Ohio sells CDI elements for a couple of dollars less than buying direct from CDI. I also learned that, as a ham, if I buy new CDI elements from NOARD, I can send them back to CDI who will calibrate them, on a frequency of my choice, for maximum accuracy. And the price is right. I don't know how well they publicize this service, but I can not complain about their policies so far.

One thing I learned is that when a 5w element (200-500 MHz) reads 5 watts, and I put in a 50w element (200-500 MHz), it reads about 7 watts. Granted the reading is at the low end of the scale, but still unexpected. Well within the meter and element accuracy specs however. My solution was to buy 10w and 25w elements to fill in the gap.

Why would the radiation from the flue be 180 degrees out of phase? The magnitude and angle of radiation from Yagi parasitic elements can be controlled over quite a wide range by adjusting their length and spacing.

Richard, while I agree with your general premise if we are talking about DX, practical experience has shown that 100 miles or more after dark is no problem for an antenna even 15 foot off the ground.

The reality, no ham gets those pretty patterns in the book on 75 unless he is blessed with large amounts of both money and land.

I will be willing to bet a bottle of your favorite soft drink that his problems have nothing to do with such esoteric reasons as angle of incidence or absorption of a flue.

These things are second order effects in the real world. Had he stated he couldn't reach beyond 200 miles, I would have set back and not said a word. When he stated 30 miles, I stick with my original assessment.

Something as simple as removing the insulation from the wire before connecting it to the trap, or an open connector that appears to work on 10 and 15 but not 75.

I would like to have 10 minutes with that antenna and my antenna analyzer, then with the initial problems solved you could then guide him into the world of patterns Vs height and all the neat esoteric stuff to let him work his first VK on 75 using the darn thing.

I agree.

But even if people do get those pretty patterns, it's possible to work hundreds of miles, and even DX. Most people just don't seem to realize that the patterns are graphs of field strength vs. elevation angle. Even a cursory look at the graphs shows that just because an antenna is radiating most strongly at high angles doesn't mean that it's not also radiating at lower angles. (Or, for that matter, that the antenna doesn't radiate better at low angles than some antennas that do their best at low angles.) And often, that amount at lower angles is all you need to communicate.

But people have a great capacity for oversimplification, and apply it to antennas as well as so many other things.

Richard,
I suggest that until you have had a chance to
use a dipole on 160m or 80m that you not make such
disparaging comments about them. You might find
that what you think isn't exactly what 'is'. I don't
have an electrical engineering degree, but I do have
experience, and that experience says your mistaken.

Exactly. Using your favorite modeling program, analyze a low dipole and save the elevation plot and then model a vertical over real ground (and by that I mean the lousy ground most of really have) and overlay the plots. There likely will be very little difference at the "useful" DX angles. The vertical will have the advantage of *not* having the high angle response that brings in local QRM and QRN, but the gains will be about the same.

Useful DX angles doesn't necessarily mean very low angles; there is some thought that a few more hops rather than fewer actually delivers better DX signal strengths at MF. See "Equinoctial and Diurnal Path Switching" Part 2. CQ Magazine, March 2002, pp 24-29.

If low dipoles didn't have some lower angle radiation then the anecdotal evidence of world-wide contacts that I offered earlier in this thread would not be possible.

I immediately posted a correction saying the SWR *averaged* 10 at the
band limits. At one end it was 12.0. This is not inconsistent or
unexpected. I saw no point in posting the four actual SWR readings I
got at the band limits that averaged out to 10.

|>6.0 at the radio."
|>Then it was: "At one frequency, where SWR was 12.0 at the radio,..."
|
|I immediately posted a correction saying the SWR *averaged* 10 at the
|band limits. At one end it was 12.0. This is not inconsistent or
|unexpected. I saw no point in posting the four actual SWR readings I
|got at the band limits that averaged out to 10.

"Immediately" being a day later and after I had responded to the first message.

It would have been helpful to those who are trying to be helpful to state:

I measured X:1 at 3.6 MHz, Y:1 at 7.1 MHz.... or whatever.

Clearly, "averaged", "ends of the low bands" and "at one frequency" have some of
us guessing.

3967. is there a difference in quality in rooftop tv antennas?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-08-27 15:53:20 UTC
From: aaronep@pacbell.net
Message-ID: <8cf398a0.0208270753.ba8856a@posting.google.com>
Source record: 135808

I desire to purchase a new rooftop antenna, approx 50 elements, 120
in. boom length. Would it make a difference in terms of antenna
life, reception
quality, in choosing between the various brands out there, ie: Radio
Shack,
Channel Master, RCA, Winegard, etc.?

I do not wish to have to climb on the roof every other year to replace
an antenna.

All replies welcomed!

Aaron in N. Hollywood

Mark,
After a quick peek at the specs, I'd think it would
work okay for short to medium length runs. If you have
a mess of it already, why not? If you have to go looking
for it, I don't think it would be worth the trouble.

That comment is a big key to helping me unscramble my confusion.
Semantics and definition problem on my part. The primary and/or only
function of a balun is to reduce circulating currents. Impedance
matching is another topic. But sometimes the two functions *can* be
combined in one widget at the feedpoint. Now it all falls into place.

I dunno . . I came into ham radio as a Novice just after the Novice
ticket became available. The old farts back then moaned and groused
about kids getting on the air with only a 5 wpm code test. Maybe we're
just the next-gen old farts. I certainly enjoy ham radio as much now
as I did back then. With two big differences: I can't scamper up and
down trees and towers like I did back then and the technical aspects
have gotten much more complex and diverse. I could get under the hood
of my S-40 rcvr with the soldering iron. I pop the the top off my

TS-940 and just stare at it in awe.

Yes it is plus it's 0.260" in diameter which means you can't slip
0.250" bore beads over the stuff, ya have to use 0.313" ID beads. But
it's still lighter than the RG-8 class cables.

I have a 259B, don't know how I managed to get along without it for
all those years. But how does one use a 259B to measure the impedance
of a balun on the bench? The only other pieces of instrumentation I
have so far beyond the 259B are an swr bridge, a decent DMM and a 50
ohm dummy load.
>
>
> It won't give you the sign of the
> reactance,
>
Not directly but it can be deduced. I think. I don't have the manual
handy. Cecil posted on the subject, sweep the band with the 259B, the
reactance flips from + to - at resonance . . ? The problem with the
259B is that it has a pretty low range, isn't much help when swrs get
over 12:1.

In a mild, snow-free, hurricane-free climate like L.A., I would imagine any of the major brands will suffice. If you get a rotator, you'll need one that will hold the antenna in the Santa Anna (sp?) winds.

Source record: 135812

Can anyone tell me whether or not the Flat-Top Tee wire antenna with counterpoise (shown but not discussed much in the July, 2002 issue of CQ) out performs a regular quarter wave vertical? What is the input impedance of this antenna.

For those who didn't see the CQ article, the antenna is a quarter wavelength vertical with the top third forming the top of the tee and acting as a capacity hat.

Is this antenna discussed in any of the ARRL Antenna Compendia or in the ARRL Antenna Book?

Thanks.

Let us ponder this for a second.
If the purpose of the radials set in the ground are to help with the grounding of the system, it would make sense to me that if they were bare, they would conduct better to the actual earth ground and therefore work better...
of course this is just a wag on my part.....

Trying to read 5 watts on a 50 watt scale yields plus or minus
50% accuracy at 5 watts. Why was your 7 watt reading unexpected?

Aaron:
There are two grades of TV antennas, consumer, and commercial as used in cable TV head ends and the like. The latter are getting extremely difficult to find, the prices are about 10X the RadShack, and they are also heavy (i. e. you need a stronger mast). Bill M can fill you in on specifics if he pops in here. Having said that, the major failure of consumer antennas are rust and plastic deterioration, and some tubing breakage. It is possible to take a RadShack antenna, beef up certain parts of it, drill out all the steel rivets and replace them with stainless bolts and lock nuts, coat the plastic with UV proof weatherproofing, and have a 20 year antenna. On the other hand, off the air TV is going away in 5 years, so why bother?

Source record: 135818

Foam versions of RG-8 size coax are about as good as RG-14. Newer foam designs are always less lossy than older "standard" RG style coax. RG-14 was never as popular as RG-8, and its variants, or RG-17 and its variants, because the cost was nearly as high as 17, so there was little incentive to choose it unless the weight or size was very critical. Historically, shipboard seemed to be the major application. Foam hardline is the coax of choice for that these days. It is still being made, I saw some recently for a government repair operation where exact replacement was specified. Unfortunately, I wasn't privy to the cost.

Connect the two input conductors of the balun together and call it point A. Connect the two output conductors of the balun together and call it point B. Connect point A to the center conductor of the analyzer input and point B to analyzer ground at the connector (or the other way around). You'll probably have to keep the analyzer and balun away from large conductive objects when you do the measurement, and it won't be precise. But it'll get you in the ballpark.

> . . .

OK, Let me rephrase the question.

How much more gain is there on a three section Co-linear then with a two section.

I tried to search, but came up dry. If anyone can point me to some info or other web sites that would be great.

Thanks

Chuck

Roy Lewallen wrote:
"Why would the radiation from the flue be 180 degrees out of phase?"

Because the flue is only about 3 feet from the coax and the frequency is in the 80 or 160 meter band. Also there is evidence of insufficient radiation at low angles where some can be expected with the antenna used. We are relying on the reports.

Ken`s antenna is reported to work at 30 miles and does not work at greater distances. Were it not for radiatiation pattern cancellation at low elevation angles, a low horizontal dipole might be a great DX antenna. Anecdotes of working the world with a dummy load don`t make it the best antenna. The next user may not have the same luck.

We have scoffing at the "waveangle stuff". The FCC publishes approximate wave departure angles at 1 MHz versus surface path length It`s a part of the rules. Appreciation may be improved by a look at the numbers:
11 degrees at 500 miles
20 degrees at 250 miles
30 degrees at 150 miles
40 degrees at 120 miles
50 degrees at 80 miles
60 degrees at 60 miles
70 degrees at 40 miles
80 degrees at 20 miles

Roy mentioned Yagi parasitic elements. The earth is a reflector for the low dipole. The low dipole over earth has its energy reflected up, not toward or even near the horizon.

The image of the vertical antenna is very different. It produces maximum radiation at low elevation angles.

Vertically polarized radiation from Ken`s inverted-V should fill-in the sky wave beyond 30 miles. It does not.

Bad coax would not be worse at 80-160 meters than at 40 meters.

A too-short antenna seems to be exciting the zenith well enough because Ken reports working stations 30-miles distant at night which he can not work during the day.

My speculation is that, removed from the vicinity of Ken`s house and in the clear, the low inverted-V would work stations well beyond the 30-mille limit he has now. I speculate the antenna does not work as it should because it is near the house.

I agree the flue is not resonant at 80 or 160 meters, so it is not cancelling all vertically polarized radiation, but it is close coupled. Point is, Ken does not get enough vertically polarized radiation to relieve his situation.

Antenna performance is as surely a function of its environment as it is of the wire configuraton. A very low dipole isn`t consistently going to reach far via the ionosphere. It will reach near. A short vertical antenna can span the globe. You probably have heard DX on a mobile radio.

Best regards, Richard Harrison, KB5WZI

The "connection" to the ground is more by electromagnetic field
(capacitive and inductive) coupling than by conduction. So insulated
wire works as well as bare wire. Insulated wire is also less subject to
corrosion.

Please reference job number: BL082202-01

Our Client is a well established company that designs, manufactures, and markets electronic communications equipment for diversified telecommunication industries, and the radio and television broadcast industry.

RF Design Engineer

Seeking a highly motivated individual to join our team. We are developing state-of-the-art wireless telecommunication and broadcast radio equipment operating in the 400MHz-8GHz frequency range, and all aspects of radio transmitter / receiver system design, incorporating Windows based components into multi-layer PC boards. Position requires close work with PCB designer and integrated schematic capture software packages (ACCEL).

Experience should include Crystal Oscillator, Low-Noise Synthesizer, Linear Power Amp, Low-Noise Preamp, Optimized VCO, RF Modem, Microprocessor Interface, and Analog/ Digital Audio.

Must be able to communicate, document, and certify the design-to-release cycle for the benefit of others. Must carry final product responsibility into pilot run, production, and tech support phases, and be able to multitask and manage time productively.

Candidates will posses a 4 year degree minimum, (or demonstrable equivalent work experience) and 5+ years experience.

Ken,

You are sending everyone spare with your expression of possibly unreliable, usually partial observations in a haphazard way. (One could be forgiven for thinking it could be one of the best wind-ups perpetrated here for w while!)

Somehow I think that theses observations are based on essentially the ***same*** configuration that you have described under about four threads.

For avoidance of doubt and some risk of clarity, lets talk about the 80m band (or 75 or whatever you call it over there) exclusively here.

It seems that the antenna you are using is a commercial wire antenna of about 100ft with some lumped reactive elements, possibly also parallel dipoles, intended for multi-band operation down to 160m. The manufacturer seems to suggest that it is designed to be fed with 50 ohm coax and deliver a bandwidth (on 80m) of ~50KHz with VSWR<2 with a caveat: subject to height of installation and ground configuration.

If the antenna actually works like this, then feeding it with 100ft of RG8X is reasonable (losses, even under VSWR=2 of 100ft of RG8X at 3.6MHz (or thereabouts) is reasonably acceptable. If you use some kind of balun device at the antenna that is intended for use on the end of a 50ohm coax, it will probably perform acceptably (ie reasonable loss, minimal derating of its power handling capability) at VSWR<2.

Remember that the VSWR you measure at the transmitter end of the coax is lower than exists at the antenna end of the coax by virtue of the cable losses. In the case of the situation described above (cable type, length and frequency), VSWR at the transmitter end of the cable will be 1.8 when it is 2 at the antenna end of the cable.

Now, if you want to use it like the manufacturer intended (that's why you purchased it wasn't it?), you need to try to find the (narrow) frequency band where it does exhibit these characteristics. You may want to try and shift that operating band to a more convenient frequency band.

The manufacture suggests that the antenna will cover the whole of the band with the help of a tuner. We might interpret that to mean that VSWR will increase significantly, and with the help of a tuner you will still be able to develop rated transmitter power into the tuner / feedline / balun / antenna subsystem.

Let's consider the effect of increasing antenna VSWR on the system:

Understand that your balun device might not have acceptable losses and its power handling may be derated when operating on loads significantly different to 50 ohm resistive.

Cable losses increase when operated at higher VSWR. For that reason, for the feedline configuration described above, I recommend you do not exceed VSWR=3. Cable power handling capability will also be reduced.

If you introduce an antenna tuner to transform the load impedance at the radio end of the feedline to suit the transmitter, the tuner will introduce losses, and the losses will tend to be higher at higher transformation ratios (generally associated with higher VSWR).

Ok, If you measure VSWR on your operating frequency at the transmitter (in this configuration) of less than about 2, that sounds like the feed arrangement is working acceptably.

If you measure VSWR on a frequency in the 80m band at 12 for the above configuration (as you previously reported) or numbers like it, and use a tuner to load the radio up, you will lose most of your power in the tuner / feedline (receive will be similarly affected).

Owen

PS: Nothing in this response should be interpreted to attach any special importance to any magical value of VSWR in a general sense. However, if a given is using 100ft of RG8X at 3.6MHz, cable losses become unacceptable (IMHO) with VSWR above about 3. To the extent that managing cable loss is a wothwhile objective, measuring the VSWR on the RG8X is a legitimate source of information in establishing reasonably efficient operation of the feedline.

I don't believe it's valid to assume that induced current in the pipe is to blame for the failure to communicate and, from there, infer a current magnitude and ratio in the pipe. With generously low ground impedances assumed and a resonant pipe, the field strength is reduced by less than 4 dB. In the model, at least, the signal strength loss is due to ground system dissipation. If the pipe is longer or shorter, the effect is even less, and the angle of current induced in the pipe varies considerably with length.

>
> The image of the vertical antenna is very different. It produces maximum
> radiation at low elevation angles.
> . . .

So let's look at some numbers. I don't know the details of the inverted vee, but an inverted vee has nearly the same elevation pattern as a dipole. For a fair comparison, the dipole height should be lower than the inverted vee by an amount equal to 1/3 of the vertical distance from the apex to the ends. But I'll use a 30 foot high dipole to illustrate my point.

At 3.8 MHz over average ground, a quarter wavelength vertical with 8 ground radials produces a field of -1.2 dBi at the elevation angle of it strongest radiation, 25 degrees. At that angle, a dipole up only 30 feet produces a field strength of -0.1 dBi, actually stronger than the vertical. Over poor ground, the vertical is best at 27 degrees, where its field strength is -1.9 dBi and the dipole's is -0.1 dBi, an even bigger difference in favor of the low dipole. Who cares where the radiation is maximum? What you should care about is how much radiation occurs at the angles you need for communication.

The angles used at 3.8 MHz aren't the same as for 1 MHz, but let's take a look at a couple of the angles listed, anyway.

Average ground

Angle Vert Dipole
11 deg -3.0 dBi -6.5 dBi
20 deg -1.4 dBi -1.8 dBi

Poor ground

Angle Vert Dipole
11 deg -4.1 dBi -7.0 dBi
20 deg -2.2 dBi -2.3 dBi

So over average ground, the low dipole is only 2.5 dB weaker than the vertical at 11 degrees elevation angle. This means that 100 watts to a low dipole will do as well as 56 watts to a vertical at that angle. Over poor ground, the difference is even less. This is nowhere near enough to explain the failure to communicate at all, while others routinely make cross-country contacts on this band with a few watts.

This result can easily be seen with EZNEC, even the free demo version. I assumed 18 ohms of ground system loss for the vertical. MININEC type ground with an 18 ohm load at the base was used for the vertical and High Accuracy type ground for the dipole. You'll find that a low dipole looks even better compared to a vertical as the frequency increases, even if you keep the horizontal antenna the same height in terms of wavelength. That's because the ground looks more resistive due to shallower skin depth at higher frequencies, and its resistance has more effect on the vertical than on the dipole.

People need to get over the tendency to look at an antenna as radiating only at one angle. All antennas radiate at all angles, and you need to compare them at the angles of interest, as I did above.

Roy Lewallen, W7EL

I assume you're referring to the post from 8/25 where you said:
"Edition 19 of the ARRL Antenna Book shows on page 3-11 patterns of a
full-size,
non-drooping, dipole with real, not imagined, ground clearances.
Propagation gets good at 1/2-wavelength height."

"Compare the groundplane vertical antenna patterns on page 3-13. A
groundplane up only 1/8-wavelength has good low-angle radiation. The
effects of good ground conductivity are apparent in Fig 16-A."

You're comparing vertical-plane patterns for a groundplane antenna
above flat ground and a horizontal half-wave dipole. What you want to
talk about is the low-angle radiation from Ken's antenna, not the
"vertical component of this radiation".

Let's look at those patterns you refer to (I'm using the 18th
edition). All the patterns in Figures 12, 13, 14, and 16 appear to be
referenced to a dipole in free space. For the 1/8-wave groundplane
antenna above real ground (Fig 16A), the max radiation is at a
take-off angle of about 20 degrees. The relative gain is about -8.5
dB. For the horizontal half-wave dipole 1/4-wave above real ground
(Fig 13A), the relative gain at 20 degrees elevation is about -18 dB.
So for these patterns, the horizontal dipole is about 10 dB worse than
the vertical at angles around 20 degrees. Is that significant? Not
really.

Consider something else. The relative gain for the horizontal dipole
(Fig 13A) is -8.5 dB at an elevation angle of 45 degrees. This gain is
identical to the vertical's gain at 20 degrees. The dipole achieves
the same gain as the ground plane, but at an elevation angle that is
25 degrees higher. Is the dipole significantly worse than the

vertical? Not really.

Maybe it's the particular design with coils that Ken has. The bands
that don't work are related to the antenna wires that have the coils.
If something didn't get installed right, the performance could be
degraded. Did you bother to look at the web site Ken listed? 73,

High Chuck,
My 16th edition of the ARRL antenna book states that 2 collinear elements have 1.6dBd, 3 have 3.1dBd, and 4 have 4.2dBd. This is theoretical, and I can't vouch for the theory, or the reality, either, but those are the numbers according to the ARRL. You might want to cough up some money for a modeling program if you plan on doing much of this stuff, or, at least get a copy of the Antenna Book.

Roy Lewallen wrote:
"So over average ground, the low dipole is only 2.5 dB weaker than the vertical at 11 degrees elevation angle."

Then, Roy would probably not dispute the 19th edition of the ARRL Antenna Book, page 3-4:
"Practical installations for 160 and 80 meters rarely allow amateurs to put up a horizontal antenna high enough to radiate effectively at low elevation angles."

The situation over excellent ground and sea water favors a vertical over a horizontal even more. Sea water is a short circuit to horizontally polarized waves. Terman says so in three different places in his 1955 edition. Marconi knew this. Hence the Marconi antenna is a vertical.

Please note that Ken wrote:
"I live in Huntington on the north shore of Long Island Sound. My house is on a neck that extends to the north."

OM I'm not certain if I have the right antenna but if you are referring to the T2FD, a type of folded dipole with the resistor at the feed point then I have some anecdotal performance measurement for you. The observation was in a three way qso on 75 meters at night with only moderate QSB. One station about 300 miles North of San francisco Bay Area was running the B&W terminated dipole. Myself and the other local station were using dipoles. Considering the vaguaries of most s-meters we took a best guess at the amount of attenuation when the T2FD station swithced ab style between the B&W and an ordinary dipole. We concluded, on balance, about and at least a 10db difference favoring the dipole. There's been quite a bit of prior discussion on this topic on this newsgroup but I'm not sure how to access the archives.

See law of reciprocity-, and a 12 to 1 SWR says you do not have the antenna set up correctly. Is there no one in your area or local club with an analyzer?

I am beginning to feel that your notes are more designed to evoke responses than to solve any problems. What is the SWR on the antenna every 100KC from 3.5 to 4 Mc?

Are you really interested in solving the problem?

>balun / antenna subsystem.

Yes, I think you have hit the nail on the head. The acceptable,
resonant bandwidth for the 80M and 160M bands is quite narrow. The
manufacturer discloses this, but also states that a good tuner will
give you good results across the bands. While it is true that a
wide-range tuner will tame SWR=12.0 down to 1.0 at the radio for this
antenna, this does not appear to be a desirable way to operate because
as much as 95% of the power will be lost in the coax feedline. This
part never was mentioned in the manufacturer's literature. Since I
intend to operate over more than 200 KHz , I need to do something.

That something appears to be adding and subtracting to the wire of the
antenna to move resonance to the middle of where I want to operate in
each band. Then -- because SWR of even 8.0 at the radio will give
unacceptable losses in any form of coax -- I want to switch to ladder
line.

However, one poster here has suggested that this will just shift the
losses to the tuner. No one else has confirmed this and it runs
counter to the the conventional wisdom that ladder line is helpful for
where the antenna is not resonant and SWR is, therefore, high. After
all, what is gained by moving the 95% loss from the coax to the tuner?

Another poster has suggested that there is no point to using a loaded
dipole if you are using ladder line, the implication being that ladder
line will let you get out an equal signal on any piece of wire.
However, it seems to me that if the loading coils lower SWR in a
particularly non-resonant part of a band from, say 30, for a plain
wire to, say 8, for a loaded wire, you have helped matters. Am I
wrong?

Now, you suggest that my description is incompete and that does not
help matters. Well, my situation seems pretty common to me and I am
using very common off-the-shelf components. I am surprised that it
has turned out to be so complicated, with so many different and
inconsistent opinions. It seems to me that my problem should be a
common one with general solutions.

Anyone using one of these shortened dipoles and coax (which is the recommended combo) will be seeing the same very high SWRs and unacceptable losses. Yet I found no discussion of any of this when I read the evaluations of the various shortened dipoles. Rather, the impression is given that a good tuner will solve all problems if you can tune to SWR=1. Not so -- as you confirm.

Well.. the specs for RG14 (Loss is less) than LMR400, and almost as good as 9913. I've heard that the spiral air core of the 9913 requires some serious connector sealing. At 100 meters on 28 Mhz:

RG14 2.2 dB
LMR400 2.6 dB
9913 2.0 dB

Guess I'll try the RG14 since I ended up with a couple hundred feet with N connectors on it.

>Are you really interested in solving the problem?

Yes, I am and I think I know what it is and there is nothing wrong
with my rig or anything I have done. It is simply a characteristic of
this kind of loaded dipole to have very narrow resonance and high SWR
elsewhere in a band. Coax has unacceptable losses where SWR is high.
The fix appears to be going to ladder line or using a different
antenna. I now think I understand this -- thanks to the discussion
here -- but don't see why it has generated such emotion.

In the 80M band, I get the following untuned SWR readings on my RS
digital SWR meter at the radio, which are roughly confirmed by the
two-needle meter on my MFJ-986 tuner:

3.325, 13.0
3.600, 12.38
3.700, 11.37
3.800, 7.44
3.850, 3.56
3.900, 1.62
3.925, 3.26
3.999, 9.27

There is sumpin WRONG with dat antenna! And I don't mean just a high takeoff angle. I would be willing to stand corrected if Ken could work other stations in the locale out to a couple hundred miles.

Many people erect antennas with high takeoff angles on purpose for state qso parties so thay have decent local coverage. A person may not even want a low takeoff angle ever if they only plan on working locally.

> But people have a great capacity for oversimplification, and apply it to
> antennas as well as so many other things.

Here I would say that a lot of people are drastically over-complicating the problem.

Now back to Ken:

Ken, as you noticed, you are getting some conflicting information. Conflict or not most of the information is 100 percent correct. You really need to do a little basic research on antennas so that you can sort it all out. I hope I'm not being rude - it's just that you are being overwhelmed with all the info you recieved.

This whole topic area has been beaten to death in the nearby and very
informative thread "Air Wound Balun Design Info?". See Roy Lewallen's
posts. Personally I'd wire the coax directly to the ladder line and
install a string of ferrite beads on the coax at the point where the
coax turns toward the shack or lands on the ground. Feedline radiation
is a good thing with g5rv's, it at least partially fills in the deep
nulls in the patterns found on the higher bands.

Hi Ken,

Tuners run out of steam when pressed hard in the 160M band. 80M isn't
all that far away. There, you can run afoul of marginal designs or
sail right through. This means that the losses don't "have to" find
their way back to the tuner with a shift in antenna design.

You are steadily moving toward a generic solution that is best
illustrated by a tuning technique published by Cecil Moore who,
uncharacteristically, has only made one contribution to this thread:
>cheers, CAM http://www.qsl.net/w5dxp
Follow the lead, study the method, absorb the rationale and it should
come together.

If it is specifically RG-14A/U, it is not very new. I would measure the loss at the frequency I intended to use it before I buried it or pulled it up a tower. I've seen several cases where that step would have saved a lot of grief and wasted effort.

I have been experimenting with a homemade HF loop, and am having troubles matching it. I have a high power variable cap on the way from Henry Radio, and have been experimenting with a coax matching stub. I can get the thing to resonate to a 1:1 swr, however after prolonged TX, the coax begins to burn on the end. I have even tried RG213 which is supposed to be good for 4KV. Am I doing something wrong?

Thanks,

Max

Ken,
On 80 meters it's obvious that the antenna is resonant
around 3.900 Mhz. Trying to use it at 3.5+ Mhz is just not
going to work very well, especially with a 'shortened'
antenna. It won't make a lot of difference if you're using
coax or ladder line to feed the antenna. You can only
'stretch' an antenna so far.

Hi Max,

The description is a little difficult to follow, but I would guess it
(a stub?) is doing what it was designed to do - what you "want" it to
do may be another matter.

You say you can resonate to a 1:1 - but be advised that means nothing
following the tuner where it is still a jungle. You also describe the
coax being burned on the end. Burned by excessive current, or burned
by excessive arcing? If by arcing, you have to derate the cable's
breakdown specification by dividing it by the SWR.

Ken,
The 'thing' about 95% loss of power in the tuner
is just not true, in general. There is some loss,
but except for maybe 160 meters, it's not going to
be anywhere close to 95%. That depends on the specific
tuner, naturally, (all of them are not created equal).
I won't try to offer an alternate for your antenna,
you know your situation better than I do so should be
able figure out something. Good luck.

Ken wrote:
"I get the following untuned SWR readings---."

At 3.9 MHz, 1.62 doesn`t look too bad. Guess that`s not the frequency Ken wanted.

The 19th edition of the ARRL Antenna Book has the impedance of a center-fed 66-ft inverted-V dipole at various frequencies over average ground with the associated SWR and loss. It appears in Table 2 on page 26-3.

Ladder line is used. Coax loss should be higher in proportion to its matched loss ratio for the same mismatch. Ladder line db/100ft is listed as .02 at 1 MHz. RG-8 coax is listed as 0.1 to 0.2 db/100ft at 1MHz, depending on available choice. So, coax could be 10 db lossier than ladder line for the same mismatch, but a 450-ohm line is not going to have the same mismatch as a 50 or 75-ohm line. From the range of impedances in the table, the coax would usually have a larger mismatch. Ken may have a balun with a ratio designed to improve matching to the coax by his loaded-V antenna.

Best regards, Richard Harrison, KB5WZI

I see a typo in my table: The first reading was at 3.525 MHz, not
3.325.

The plan at this point is to add a one foot pigtail to the outboard
end of the 80M sections, which the manufacturer's modeling program
says will bring resonance down to the low end of the band.

The question remains just how far can you "stretch" this kind of
antenna, if you are using ladder line.

Max,
Usually, a 'matching section' is made from 75 ohm coax,
but if you're doing okay with the RG-213, good enough (but
I don't understand how that would work). The first solution
that comes to mind for your 'burning' problem is to reduce
power. I'm taking for granted that your running more than
100 watts, right? Not that 100 watts is a limit for using a
'matching section' to feed a loop.

Source record: 135760

I also have a little Bird 25-175 MHz wattmeter with 150 watts fwd and 15 watts reflected, a 10:1 ratio. If the meter is reversed, I get 15 watts fwd and 150 watts reflected. I can hook a transmitter to it, set it for 15 watts on either scale, reverse the meter, and it still reads 15 watts. Granted, I'm not swapping elements, just twisting a switch, but two different sampling loops must be involved.

Also, similar accuracies are seen on most multimeters when changing scales.

The Bird's 30 uA meter has an expanded scale at the low end, so it's very easy to read down to 1 watt with a 50 watt element. I guess I just expected more consistency between ranges. The new elements should reduce the amount of error when switching ranges, hopefully.

Don't generalise the outcome of your 100ft of RG8X to all coax
feedlines. If the coax has lower loss (better coax or shorter) the case
is better. The converse applies.

> part never was mentioned in the manufacturer's literature. Since I

Funny, that!

Just for the excercise, and what you may learn from it, work out the
VSWR seen by the transmitter connected to 100ft of RG8X at 3.6MHz with a
short circuit at the far end (that is right, no antenna, just a short
circuit).
Most t match tuners like your MFJ should transform the impedance
presented by the cable (3.6+j18.1 on my reckoning - well Winsmith's
reckoning and help from two of my friends - Mr Hewlett and Mr Packard)
to 50ohms, the rig will see 50ohms or VSWR=1, but 100% of the output
power is lost in the tuner and cable.

Owen

(The answer to the riddle is VSWR=15.8.)

Ken,
How far can you 'stretch' it using ladder line?
I honestly don't know. Further than if you were
using coax, but even so, it'll never 'stretch' over
all of 80 meters. I would have to guess that 160m
is going to be even more narrow, but still no idea
how much. I'm sure I'm not telling you anything 'new',
but never believe the manufacturer's claims about
antennas! Those claims are always for the 'best' case
installation, and seldom matched in the 'real world'.
It looks like you're learning like I did, the hard way.
(I know it isn't funny now, but it will be 20 years from
now.)

I am considering running a 30 foot trench from the base of my tower to my ham shack for my coaxial cables, and would like to here comments / suggestions from anyone that has done this before, on things to do / not do, etc.

All of my cables are 9913, and I have a bundle of about 8 feedlines.

I am thinking about a inch conduit, and wondering about a few things: (BTW, I live in Southern California)

How deep should the trench be below ground?

What kind of pipe is best to use?

Should I drill holes in the bottom side of the pipe so water can drain out?

Should I place some gravel on the top of the trench before I lay the pipe on top, to help with drainage?

Anything else I should know?

Thanks for your help.

Herb - KG6OK

Looks to me like you are observing VSWR around 8 about 100KHz off centre. Given the loss in your 100ft of RG8X, the VSWR at the antenna end of the cable is around 16.

If you used 100ft of 9913 instead of the RG9X, we might expect that you will observe a VSWR of around 12 at the transmitter end (when the antenna end VSWR=16). This isn't necessarily worse... the line loss (mismatched) is now around 1.5dB instead of around 3dB with the RG8X.

Applyign the same technique to a narrower band, it looks to me like you are observing VSWR around 4 about 50KHz off centre. Given the loss in your 100ft of RG8X, the VSWR at the antenna end of the cable is around 5.

If you used 100ft of 9913 instead of the RG9X, we might expect that you will observe a VSWR of around 4.5 at the transmitter end (when the antenna end VSWR=5). The line loss (mismatched) is now around 0.5dB instead of around 1.2dB with the RG8X. I would be pretty happy with line loss of 0.5dB if your antenna tuning unit can reasonably efficiently transform the load for the transmitter.

Therefore, one possible solution is that you could throw a bit of money at some 9913, shorten the length between the tuner and the antenna if you can (including don't run RG58 tails in the shack), relocate the usable band to be more convenient, and you have 100KHz of coverage with tolerable efficiency from your multiband antenna on 80m.

If we're talking about a short loop, then the voltage on the matching cap can be extremely high even with only 100W, depending on the loop size and other factors. You need a HV vacuum cap.

Herb,
The trench should be deep enough so that you can run a lawn mower over it when it's filled in. Don't drill holes in the bottom of the pipe for drainage, the idea is to not let water in. Use a "U" at the 'stub-out', and seal it some way. PVC pipe works well. Instead of gravel (which will work), I'd use sand, less chance of poking a hole in the pipe. No matter what size pipe you decide on, you'll always wish it were just a little bit bigger later. And always leave a rope 'loop' in the pipe. Lets you pull something through it later.

Hi:

I would add to this, use 4" PVC electrical conduit. I you are going to have any bends, use the wide radius "sweeps" that are available for this pipe. Glue the joints very well and water will not get in. Don't drill holes, as the will just let the water in. I have 65' with one 90 deg. bend in my setup. I buried mine down about 18" to the bottom of the trench, so there is about 14" of dirt over it. For grounding, I laid #6 bare copper wire in the trench with the conduit, it's connected to the grounded tower and to 4, 8' ground rods spaced along the 65' run with the last rod just before the ground wire enters the house. Mine comes through the basement wall were there is a copper ground bounding panel that connects the lighting arrestors the ground wire from the tower and the house ground at the power panel. This was required by code and was the only thing the inspectors cared about other than the height of the tower.

If I can be of any help with advice contact me.

> with the G5RV.

It is good engineering practice to install a balun or choke at every balanced to unbalanced transition point. A choke at the coax/twinlead junction on a G5RV will tend to reduce feedline radiation and RF-in-the-Shack. Quoting the above web page:

"It is now known that if a balun is connected to a reactive load presenting a vswr of more than about 2:1, its internal losses increase, resulting in heating of the windings and saturation of its core (if used)."

This is a pretty ridiculous statement. An SWR of 2:1 is close to a good match. In general, the differential current fields in a balun tend to cancel and the differential voltage/current are what we measure to obtain SWR. Baluns are stressed by common mode conditions which most of us don't bother to measure.

"However, later experiments and a better understanding of the theory of operation of the balun indicated that such a device was unsuitable because of the highly reactive load it would "see" at the base of the matching or "make-up" section on most hf bands."

This is a half truth. On the bands where the G5RV performs well, i.e. 80m, 40m, & 20m, the impedance at the coax/twinlead junction is not highly reactive and a 1:1 choke will perform its intended function. Take a look at the charts on my web page to find out why the above statement doesn't apply to 80m, 40m, & 20m (also 12m).

What is the name of the type of antenna connector used in the TH-G6A?

Are loose solder or crimp type connectors available? I need to build an external antenna for this radio and would like to get hold of the correct connectors or alternatively an adaptor to BNC.

What other options do I have? My old TH78 was BNC and made life really easy.

I hope you didn't misread what I posted earlier. Ladder-line will shift the matching problems from the antenna to the tuner where they are easier to solve. Take a look at my All-HF-Band-Antenna on my web page to see what is possible. I use a single 130ft dipole, fed with ladder-line, without an antenna tuner, and cover 80m-10m. If your ladder-line SWR is not too high and you feed the transmission line at a current maximum point, you may not even need an antenna tuner.

Being able to get a 1:1 match and being able to do so with low loss is another matter. I'm not saying the '986 is a lossy tuner! But without knowing the opeerating conditions it's hard to know what the system efficiency really is.

>
>>Changing to ladderline is a last resort, and negates the need for the
>>Alpha-Delta.
>
>Could you elaborate on this please? Do you mean that I could just use
>a 100 ft long dipole (or whatever I could fit) and just tune that on
>160-10

Yes - in fact the longer the better.

The reason the Alpha Delta is so complex is so that it will provide a decent match to coax on several bands. With a tuned system (dipole and low-loss feeder, matched at the transmitter end), that complexity is not needed.

However, it's important to note that such a system may present some really weird impedances to the tuner. It's also important to note that performance on 160 will be limited because either antenna is quite low and short on that band.

>(because high SWR wouldn't matter)?

It is inaccurate to say that "SWR doesn't matter". Rather, SWR matters less when you use a low-loss feed system.

Think in terms of the feed system as a whole. For example, compare a 50 foot length of RG-213 operated with a 9:1 SWR on 3.5 MHz with a 500 foot length of ladder line operated with a 3:1 SWR on 28 MHz.

>Would it radiate as well
>as my multi-wire dipole on 10 and 20 where it has separate wires?

I don't think you'd notice any difference. But since you have EZNEC, why not model both antennas and see what the results are?

>Or
>do you mean that the 40-80-160 wire with the coils would be
>unnecessary and a simple 50' wire would do the job just as well?

I don't see any reason to use multiple wires with an open-line-and-tuner feed system.

--

Here are some other considerations:

- Do you really need 100 feet of RG-8X to reach from the shack to the antenna feed point?

- Could the shack location change? (I've always favored a basement or first-floor shack, for grounding and feedpoint reasons).

- What sort of results/operation are you looking for on 80 meters? DX (thousands of miles) or regional/local? (dozens to hundreds of miles)? 'Phone, data or CW? Ragchews, nets, dxing, contests?

Source record: 135697

And if you were trying to put together a system guaranteed to work over a given path during specific hours 365 days a year, then I to would follow the given advice.

Your problem is simple, your trying to go from DC to Daylight with a single antenna. Any resonant dipole on 75 will have a 2:1 bandwidth of about 170 KC, if you fatten the antenna by making it a cage, depending on the diameter, you can get about 300KC.

Adjust the resonant point of your antenna from where it is and go from there. My solution given that you have a tuner would be to get a G5RV. HRO and other goodie stores have them for about $40 with ladder line, inline choke and coax lead in. In spite of all the negatives you hear, I have worked over 200 countries on 75 with one. Is it the best antenna in the world, heck no, does it work for someone interested in working all bands with a minimum of effort... Sure does, and besides it irritates the hell out of the diehard 160 bunch when you tell them your running a G5RV.

Another thing you can do is to add a second set of wires from the trap that are longer than the set that is on there. Separate the far end by at least 5 feet and your bandwidth will increase as well. Art Collins had a dual dipole connected this way and covered all of 75.

I guess what I am sayingis that there is a vast difference between the needs of a ham and the engineered needs of the short-wave broadcaster. If everyone listened to what the experts tell you is necessary to communicate, none of us would have ever made a contact.

Good luck and I will probably work you before I work someof the experts that are still determining the takeoff angle of their sterba curtains and calculating their ground conductivity to the 14th decimal place.

Hi Ralph,

The old NBS is now the NIST (National Institutes for Science and
Technology).

During my time at the bench, I saw a lot of Birds come in for tune-up.

UNIVERSALLY and across the board, they required adjustment after 6
months of use, EVERY 6 months. They were submitted not because they
were used as lab instrumentation (far from it); but rather because
they were used on a flight line where FAA mandated all measurements be
traceable.

The Laboratory version of this style of design (a separate, tuned
cavity probe) was found in the Sierra AN/URM-120. Other manufacturers
made this under government contract.

The major source of error for Birds is found in the parts that move
(aside from the meter). The input and output connectors are poor and
introduce SWR on their own. The turret can suffer alignment problems
due to parts erosion. This may sound rather insubstantial, but
geometry is everything and error shows up quite pronouncedly (compared
to a standard).

For example, in making a twist in the turret on the Bird, you may not
go a full 180ï¿½ because the bayonet pin is slightly gummed up with
erosion debris (much less bent and you hit 185ï¿½). Instead you get
175ï¿½ and accuracy literally skids from there.

I have never seen a Bird Power Meter that was in specification.

Every URM-120 that I saw was 90% within calibration (on average with
probably half at 100%).

Thanks for the vote of confidence in the Sierra meter. I bought one several years ago at a hamfest. Someone was selling a bunch of them that were still in the sealed box. They were probably 5 or 10 years old but had never been out of the origional packing. It was in a sealed cardboard box that had some very heavy duty aluminum foil over that.

As you know and what I was trying to say is that the slugs are interchangable from one Bird meter to the next and no way can they be all that accurate. Some just expect electronic instruments to be 100 % all the time..

At work we have some caliberation instruments for temperature and pressure that are sent off once a year to be certified. They are used to caliberate instruments that are used on a production line. The computer readouts are to 3 decimal places at around 300 deg. C. The thermocouples that are feeding the computer readouts are only certified to about 2 deg. C. The main thing is that the readouts will repeat the same all the time even if they are not that accurate.

I don't remember it being discussed, but seems to me, the
reflection coefficient of any stub is 1.0 giving an SWR of
infinity at the open/short point. The question becomes not
why do coaxial stubs fail but why do some fail to fail? ;-)

|>going to work very well, especially with a 'shortened'
|>antenna. It won't make a lot of difference if you're using
|>coax or ladder line to feed the antenna. You can only
|>'stretch' an antenna so far.
|
|I see a typo in my table: The first reading was at 3.525 MHz, not
|3.325.
|
|The plan at this point is to add a one foot pigtail to the outboard
|end of the 80M sections, which the manufacturer's modeling program
|says will bring resonance down to the low end of the band.
|
|The question remains just how far can you "stretch" this kind of
|antenna, if you are using ladder line.

I'm going to take one last stab at this and then give up. There has been a hell of a lot of conjecture in this thread but very little real number crunching. All of the following is based on some assumptions, however, I believe they are good ones.

Given that the antenna is resonant at or close to 3.9 MHz and that it is a shortened, loaded, low electrical height, "vee" dipole, I submit that the real part of the radiation + loss resistance is about 29 ohm.

A 29 + j0 load on the end of 100 feet of RG-8X on 3.9 MHz will give an input SWR of approximately 1.6:1, which is alleged to be the measured SWR. The alternative is that the resistance is about 89 ohm which is doubtful in my mind.

The total line loss for this situation is about 0.6 dB.

Skipping to the "almost" bottom of the band, 3.525 MHz, the measured SWR is 13:1. If anything, at this frequency the real part of the load Z will be lower than 29 ohm, but how much is unclear, so I will keep it constant and assume that only the reactance changes.

A 29 -j420 load will present a 50 ohm 13:1 SWR at the input end of the line and the total loss will be just shy of 10 dB. (Note: the SWR on the line will actually be higher than 13:1 due to the line reactance, however, the measuring instrument is calibrated to 50 +j0)

Going through the same exercise for the other frequencies I construct the following table:

Freq SWR(50) R X loss

3.525 13.0 29 -420 9.8
3.600 12.4 29 -337 8.1
3.700 11.4 29 -260 6.3
3.800 7.4 29 -133 2.9
3.850 3.6 29 -61 1.2
3.900 1.6 29 0 0.6
3.925 3.3 29 + 55 1.1
4.000 9.3 29 +175 4.0

Replacing the coax with 100' of Wireman type 554 window line, for which I have published measured data (Zo=360), I get the following:

Freq SWR(Zo) R X loss

3.525 13.0 6790 +2904 1.3
3.600 18.3 741 -2070 1.0
3.700 15.5 189 -956 0.8
3.800 12.2 70 -430 0.5
3.850 11.2 50 -276 0.5
3.900 11.0 40 -175 0.4
3.925 11.3 34 - 99 0.5
4.000 13.5 26 + 29 0.6

Now the ladder line proponents will say, "See, I told you so, look at the reduction in loss."

To which I will say, "How are you going to match this turkey?" Look at the change in Zin with a change of just 75 KHz between 3.525 and 3.6 MHz. The real part changes an order of magnitude and the highly reactive part changes sign. This is a *very* high Q situation.

The usual hi-pass tee (series C, shunt L, series C) can match the load at 3.525 MHz okay. But move up to 3.6 MHz and for an optimum solution, you need a completely different network! The series element in the output side really needs to be an inductor. This holds true until you get to the other end of the band where you need a capacitor again. With say a 500 pF max capacitor in the output leg, about the best you can do at 3.6 MHz is a 6:1 SWR.

I do not want an antenna system where I have to reconfigure my tuner to QSY a few KHz, no matter how "efficient".

All of the foregoing calculations were done using the excellent Excel program XLZIZL by Dan, AC6LA, which can be found at www.qsl.net/ac6la.

George,
Not really any more nonsense than I've seen from
you.
As when phasing any two antennas, it's much easier
if both are 'tuned' to the same frequency. The easiest
way of doing that is to 'tune' each individually, in
the position they will be in for use. That means a couple
of 'up'n'downs' for each antenna.
If the two antennas are not the same, things get a
bit more difficult, but, it's basically the same procedure.
The 'tuning' part means making the resonant frequency, and
input impedance of each antenna the same.

>I have a what I think is a yaggi screen reflector. It looks like a widow
>screen with 8 dipoles. It picks up ch. 14-69

That sounds like an 8 bay screen reflector designed for UHF television. The FM radio band (in the USA) is 88-108 mhz, which is between ch. 6 and 7 in the VHf TV bands. As such your antenna is not going to be very directional and have lots of gain as it would if used for UHF TV.
However, since it is up in the air, it could help on some stations. The easiest thing would be just connect the center conductor of your coax to the telescopic whip antenna on the radio. You could do this with an alligator clip, or just strip out a couple of inches and wrap it around the whip. You might connect the coax shield to a ground on the radio, like on an external speaker terminal, or the battery (-) terminal, and see if that helps.
Not sure if the 30db booster would help in this application, may overload the radio, but won't hurt to try and see.

Source record: 135624

you haven't supplied quite enough information. is this a stub that is open or shorted on the end and connected in parallel with the loop? how long is it in wavelengths at the frequency you are using?

An open ended stub can develop quite high voltages on the far end depending on its length. if you have simply cut off the end flat to tune it the short air gap may develop corona. to prevent corona developing at the far end you can cut back the shield a bit and seal off the end with good electrical tape.

a shorted stub can develop high currents at the far end, again depending on its length. if this is what you have be sure you have a good electrical connection between the center conductor and shield.

Replace the coax with 130' of Wireman type 554 window line and the
system will probably resonate just about where Ken wants it resonant.

That's a pretty special case, most of us'ns prefer patterns which are
as omnidirectional as we can get 'em in most instances. g5rv's are
nasty things, I had an 80m version up horizontally around 65-70 ft.
for FD this year and the thing had a lot of "negative gain" spots
around the compass on 20 & 15. Annoying.

I have searched and asked here about a website that might give
'predicted' patterns for the G5RV on the various bands but I haven't
seen anything. I too notice what seems to be 'holes' in the pattern and
would like to get a visual handle on what might be typical.
Does anybody have a reference site for such data?
Tnx,
WX4A

The simple answer is yes...as long as you have a hole and the cable you can bury it. The tougher answer is still yes but one would want to know how long you want it to last. That depends on local soil conditions (drainage, acidity, etc) and the specific type of jacket on the cable (PVC, PE, etc).
I'm in cable TV work and we have specific grades of cable that are recommended for direct burial and they usually include additional 'goop' between the jacket and sheath to further repel any moisture that migrates thru the jacketing. I don't see this in the ham market.
If you want to throw 'anyole' off-the-shelf cable into a trench and live outside of the Everglades you can probably get 5 years out of it if its of decent quality. Placing it in PVC or being particular about the jacket composition will probably outlive the antennas its connected to.
PVC pipe is cheap. And cable deterioration is inevitable, aerial or underground. Its much easier to replace if its in PVC pipe.

4091. G5RV question

Newsgroup: rec.radio.amateur.antenna
Date: 2002-08-29 01:03:24 UTC
From: vhfradiobuff@yahoo.com
Message-ID: <1996cb6d.0208281703.55a3bec6@posting.google.com>
Source record: 135632

I've been thinking of picking up a G5RV in preparation for upgrading. I have a large lot that should allow me to put up a full length G5RV. On the back of my property is a wooden fence, about 7 feet high. I plan on putting chimney mounts on the fence posts on both corners of the fence and one in the center (my property/fence is shaped like a rectangle). I plan on putting a 20' pole on each end and a 20' pole in the center. With the G5RV only 20' up, completely horizontally strung, should this work ok for HF? I'd be putting out up to 100 watts. Any recommendations on how to attach the G5RV center and ends to the 10 poles? They're the kind you buy at Radio Shack for around $10 each.

Also, what would be a good coax to feed this with? The run would might be as much as 200'. I don't have a ton of cash to spend on the coax, so some comprimise is needed.

4092. Re: Trench for coaxial cables

If you are having the tower installed under a building permit, the
inspector
may have some say in the depth of the conduit. I had to hire a back to
trench
in my two 4" conduit runs (over 110 feet) between the house and the tower
to satisfy my local building inspector. He wanted it down 36", which
seemed
excessive for low-voltage cables.

I acquired an MFJ-1786 HI-Q Loop antenna at a hamfest for a price I couldn't pass up. It had no documentation. I down loaded the manual from the MFJ web site, but they do not provide schematics. Does anyone have a schematic of the "Deluxe" remote control unit and for the antenna it self? I would prefer a scanned image file that you could e-mail. I am willing to pay postage if you don't have that ability.

Thanks for you help - Jeff - KA9S

G5RV isn't as bad as everyone says. I use the 'junior' version (40-10)
and its about 40' in a tree on one end, 30' on a mast at the center and
15' on a 2x2 at the other end. I've had better antennas before but for
simplicity I can't complain too much with this one.
But....since you have a 200' run, you'd probably be just as well off
with any 100-150' dipole fed with twin-lead and a tuner. There's no
particular magic about a G5RV that would make it better in such a
situation.

As I understand it, the radials you lay on the ground will become the "ground" as far as the antenna is concerned, so you can use insulated wire.

Any other ideas, real experience with this type of antenna out there?

Cecil:
I had to replace the water system at the farm in South Texas where we had battled gophers as far back as I remember. I wanted to replace the 50 year old iron pipe with PVC, for obvious reasons, but worried about the *(&%&^ gophers. I read up on them, and they have a maximum depth they rarely exceed. I buried the pipe about 28" deep I think (this was 25 years ago) and have not had any problems. Read up on gophers.

Now, someone tell me how to keep the squirrels from shredding my halyards for their nests. Cotton, Dacron, whatever the exotic stuff is, even one run of RG-58 which got in their way became shredded. Steel conduit works there also, but is difficult to install. I thought about using barbed wire, but it won't go through the pulleys.

Any shorter than 1/4 wave radiator will be inferior to a full 1/4 wave
radiator.
The T is a pretty good antenna though. I use a version of one here on
160m.
It has a cleaner vertical pattern than an inv L. Has an overhead null
same as the full 1/4 wave. MK

check into either diamond or comet both make multiband mobile antennas
then all you need to do is look at specs and $$$ and take your pick either
is a good antenna

Joe, if your receiver has screw terminals it probably has a 300 ohm input. Easiest thing to do is buy a Radio Shack 15-1140 matching transformer. It has two leads with spade lugs that connect directly to your receiver screw terminals. The other end has a receptacle so that you can attach a coaxial transmission line directly to it. No soldering, no modifications of any kind required. The thing costs only $2.99.

Hello all,

I'm looking for the best option for running 40m to 6m and between for my jeep. It will see lots of rugged use with low hanging trees pulling on the antenna and lots of garages.

I will be running a Yaesu FT-100 and have the FC-20 autotuner.
I have had good experience in the past with the typical top loaded 4' fiberglass whip CB antennas with cb radios. They are strong, flex like crazy, and hold up to a lot.

What are my options?

Is there a flexible Hamstick pack solution that is durable and flexy?

Should I just tune a 4' 11m fiberglass top loaded? What about a 102" SS whip?

I know ICOM has that AH-2b which is some 8ft whip antenna. any problems cutting down a 102" ss whip to the same size? are there coils in that antenna?

Thanks!
Tony

Our local rat shack has a pretty high turnover, but there are two people
who have been there for some time. One is pushy - tries to sell all sorts
of stuff, the other doesn't do so but waits for me to ask.

Guess which one gets all my business - and the commissions that go with it?

I use something much smaller, with a nice regular pattern.
I have used it indoors and outdoors, it is not afeccted by the surrounding
and it's not affected by the installation height.
I have done some tests and I have the same performance at ground level or
40' high.
The SWR is flat across all HF bands, around 1.1:1.
The bigger models allow to operate indoors QRO without the adverse effects
of radiaton exposure.

Some OM's call it an artificial non radiating antenna, others call it a
dummy load.

> attract a direct lightning hit?

It is a conductor that can have a different voltage potential than the
charged cloud in the sky. So yes, it is a potential lightning target.

> Or, does the roof actually provide "some" protection (due to its being
> something of a dielectric?) ?

Yes, the roof provides some protection.

> If so, why? Differences for a wet vs. dry roof?

It reduces or eliminates any ion streamers that might rise towards the
charged cloud.

> b. Would it still be a good idea to ground the antenna mast (which would
> also ground the elements) to a water pipe in the attic?

No idea. My knowledge of discone antennas is minimal.

> -Does the possibility of a strike, or induced voltages from a nearby
> strike, go to zero if the coax is unplugged from the receiver?
> (which is what I plan on doing, but one sometimes forgets)

No. For one thing, that coax might still provide a lower impedance path to
ground than any path strictly through the air.

And induced voltages can occur in your house wiring or outside wiring that
feeds your house.

> c. A theoretical question: in the general sense, does a grounded mast help
> prevent a counter charge from being developed beneath a charged up cloud, or
> merely provide a well defined path for a lightning bolt to travel to ground?

It provides a better path to ground.

> d. From looking at some catalogs, I see the in-line coax lightning

> what I'm wondering about, is for for (b). The charge would then
> go directly to the chassis of the radio, and would
> then reach ground via the chassis' ground.

Any charge that gets to the radio is likely to get inside it as well.
Remember that that would mean a large differential voltage between the
inside of the radio and the outside.

That is why, for antennas, the coax shield is grounded in one or more
places before it gets to the inside of the house.

> As it may not be an actual strike, but perhaps a lower induced
> voltage of just enough to break the spark gap,
> what would this do to the radio (e.g., the chassis being raised
> momentarily to 100 V, or so) ?

The induced voltage is more likely to be quite a bit above 100 volts, before
the spark gap can drain off the current.

> Are both types just as safe and useful?
> Any caveats?

I don't like spark gaps. The response time is too slow and they allow
too high a voltage before arcing. There may be receive only suppressors
that don't have this problem - but I am not aware of any.

The best thing to do is get rid of any strike power before it gets
inside your house. With your setup, this is impossible as the antenna
is indoors.

I am also in the Cable TV business, although not selling coax itself. There
are "flooded" versions of 50 Ohm coax just as there are for 75 Ohm. The
suggestion of using duct for underground applications is a good one. I also
suggest that you significantly oversize the duct and leave a pull
rope/tape/wire in the duct in case you want to pull in an additional cable
later. QST lists a couple of large cable distributors. The distributors
can help you find the right cable for your application. Power handling,
Loss and cost are only starting points for selecting the correct cable.

Hi All:

In my tower installation, one of the requirement was that if I had more than 50' of coax inside the house it had to be UL listed. I don't think that any coax used in ham radio is UL listed.
The inspectors from the county didn't care how much cement I had or if there was re-bar or not or how deep my conduit was. The cared about the grounding, and the height, we have 40' structure limits here, and if my cable was UL listed if I had more than 50' inside the house.

Bill Nelson wrote:
"Any charge that gets to the radio is likely to get inside as well."

My experience with countless land-mobile base stations, which had antennas as the highest items around, disagrees.

These antennas were grounded to the tower at the top. They were folded monopoles. Coax shields were grounded at the base of the tower. These monopoles were heavily pitted from many lightning strikes. Lightning never got inside a radio. Coax with no protectors barred lightning from the radio input. It is a natural common-mode choke.

Lightning aplenty traveled the outside of the coax. It`s important to dump this energy to ground so it doesn`t enter the shack.

Lightning is a transient event with much energy in alternating current across the spectrum.. Most of this current can`t penetrate the coax or radio box due to skin effect. The rest has no effect inside the conducting radio box because the voltages are the same on all sides of the box. There is no difference of potential to drive current through anything inside the box. Power, audio, etc wires must all be bypassed to the box to limit potential differences they may have with the box and keep lightning out.

Bill wrote:
"I don`t like spark gaps. I agree they are unnecessary and useless on coax in nearly all cases.

Hi Jim,

Admitting my own bias in pursuing antennas as electrical devices, I nonetheless was impressed by the mechanical approach of the SteppIR system. Probably like yourself, I saw it at Boxboro last weekend.

Certainly it is an elegant brute force system which works by seeking a mechanical solution to tuning. For those unfamiliar, the system use a 'tape measure' dipole approach, which is controlled by motors to change length for tuning.

I would see the main drawback as the fixed element positions (I saw the three element Yagi version). Obviously there are separations which work best in terms of gain and F/B, which you don't have the versatility of changing (even though you can do some tweaking with the element lengths to a limited extent). Now this is also true for trapped Yagis in the same configuration, but such antennae do not have the potential tuning capability across many more bands that the SteppIR system does.

I heard the argument that this antenna is less lossy than trapped Yagis, a valid but probably not important point: for a 3 element Yagi, there is probably no more than a 2 dB difference max --if that. Far better to get theYagi (of any design) up another 10 feet or more to pick up the practical gain of a lower launch angle.

Anyway, it looks neat, and I am confident the performance claims are valid. It is, in my opinion, pricey, but so is replacing trapped Yagis every few years.Its up to you to see if this interesting design is relevant to your need and pocket book..

Bill,
Unless the radials are elevated, the 'dirt' is also
going to be a significant part of the ground system.
That doesn't change the fact that you can use insulated
wire for the radials, direct contact isn't necessary.
An inverted 'L' depends on a ground for how well it
works. The 'better' the ground, the better the antenna
'like's it and the easier it is to use. 'How good' the
ground is usually depends on when you get sick of putting
in more radials. You should have a number of radials
somewhere between 4 and 'fed up with it'. Less than 4
will also work.
An inverted 'L' also works better when the vertical
portion of the antenna is the longest that you can make it.
That depends on what you have available to 'hang' it from,
and what you can get away with without too many problems.
Like other antennas, there is no 'one' best way of putting
up an inverted 'L', and there's no rule that says you can't
change it later.
'Doc

The G5RV is a 102-ft dipole. Height and surroundings affect its pattern, but see page 2-12 of the 19th edition of the ARRL Antenna Book for the free-space patterns of a 100-ft dipole. The G5RV won`t be significantly different.

When you ask the MFJ helpdesk they will probably help you and send you the
schematics free of charge. I think that MFJ is careful and selective in
distributing their knowledge. If you can convince them that you need the
diagram for your own antenna and not for commercial purposes I think they
will help you. At least they helped me and despite the sometimes negative
information heard about MFJ I can only say that they gave me very good
service and
sent me very well and quickly the ordered spare parts for my MFJ 1786 and
also
the schematics for the automatic remote control.

I've built mine also, starting from scratch, and following the basic
dimensions .

I am using it as an inverted V, about 12m up in the middle and 6-7 m
at the ends. It is the longest dipole antenna that will fit in my
yard.

I have one advice: you probably will have to tweak it a bit on the
dimentions, to get the best match on all bands , for your situation
and your type of balun.

I had to shorten the dipole a bit to raise the center frequency on
20m. Then I played a bit as to where to connect the coax directly on
the matching section. .

I don't use a balun , but I use it on all bands using a transmatch
at the radio end.

I had a funny idea the other day, What if I added a reflector wire
for 20m and one for 15m ? on a 3m boom maybe 4m ...
I could even add a jumper at one end of the wire to turn it in a
director... hmmm I wonder what would happen to the other bands.

> Tnx,
> WX4A

I don't know of any websites which show the horizontal patterns for
g5rv's but the ARRL Antenna Book shows the basics. The g5rv behaves
+/- like any dipole which is more than a half-wavelength long. It has
a typical two-lobe half-wave dipole pattern on it's lowest frequency
of operation but on the higher bands the patterns have multiple lobes
with deep nulls between lobes. The higher the frequency the more lobes
and nulls. By the time you get to 10m with an 80m dipole the pattern
looks like daisy petals per the Antenna Book.
>
In the real world however the lobes don't have as much gain and the
nulls are not as deep as shown by modeling because modeling does not
take into account a number of factors like far field effects which
tend to fill in the nulls to some extent.
>
There's nothing magic about a g5rv, it's just a dipole with a trick
feed scheme.

I would check with your local building code and bury the cable to the same depth as required for buried electrical cable. That way you won't have any code issues should an inspector come moseying about. Use the same type of conduit used for Buried electrical cable. It is PVC and easy to construct, just like PVC water line. Rent a Ditch Witch gas trencher to dig the hole. It will turn a 4 hour job into 15 minutes. It will be the best investment you evermade after it is all finished. Around here, you can get one for $175 day, less for half a day.

Andy,

I use both insulated and bare wire in the ground system. No difference, and I now have about 2 km of wire at or just under the ground. It is electromagnetic coupling and although there is no difference in performance, insulated wire lasts longer. I also use chicken wire for the first 15 feet or so in all directions bonded to the master earth stake. My 160 metre quarter wave inverted L works a treat!

I have a new in the box Traffie Hex-beam for sale, it covers 5 bands, 10-12-15-17-20 mtrs;

Info on it can be found on Traffie.com I believe. Weight is 9 lbs. Wind load is 5 sq ft. and turning radius is 9 ft. Can be turned on a small tv rotator.

It looks like an inverted umbrella.

Looking for offers, list new is $890.

Jim

The coax shield was probably grounded to the tower near the antenna - and possibly at one or more points elsewhere on the tower (if it was a tall tower). The tower would also be grounded properly and there would be a ground window on the equipment building.

We are not talking about land mobile stations here - with an antenna and coax properly installed on a properly installed tower.

In the proposed installation, the only path to ground from a strike on the antenna (no matter how unlikely) is likely to be via the coax. And it would be the full power of the strike, not one attenuated by proper suppression techniques.

But I agree with your otherwise. I have experience with quite a few repeater stations, and when properly set up, there is no problem with lightning strikes on the antennas. The stations just keep on working, even in the middle of a severe lightning storm.

> Lightning aplenty traveled the outside of the coax. It`s important to

Yep. I believe that I stated this elsewhere in that response.

> Lightning is a transient event with much energy in alternating current

Everything must be bypassed etc before entering the shack. Again, that is not what the person proposed.

What you and I would do with a commercial installation is something that few Hams would bother with.

Hi Andy ,
The best Way I know of to reduce RF on a rig with a long wire is to us a
good RF ground system. a 1/4 wave Radial wire attached to the rig works
wonders. The Coax to the outside usually does not affect the RF situation
all that much with a long wire.

MMANA is a nice program, but it's based on MININEC and doesn't have the
"high accuracy ground"/Sommerfeld approximation NEC-2 based programs
offer.
If you want to model horizontal wires closer than abt. 0.2 lambda to the
ground you will need the Sommerfeld ground model. I would prefer to have
both kinds of programs at hand, i.e.
take MMANA for MININEC and 4nec from www.qsl.net/wb6tpu (unofficial NEC
archive). Latter is a NEC-2 program and has a nice graphical user
interface.

George,
Use a product called Tangle Foot. It comes in a caulking tube and
squirrels hate to get it on their feet. Coat areas they use to access
their living/nesting areas. It was designed for birds, but I have
been told it works by others that have used it. Another thing that
works for squirrels is warfarin based poisons. If you try to live
trap them you must take them at least 10 miles away and use scent
killers on all the areas they used for habitat. If you do not they or
others will use the same areas. Professionals recommend putting them
to sleep, using your preferred method.
I had squirrels that deceived my soffit area was going to be their
next home and experimented quite a bit before ridding my area of
squirrels and de-scenting the area.

Dave, KC1DI wrote:
"A 1/4 wave radial wire attached to the rig works wonders."

2, 4, 6, 8 or more radials in opposing directions are better. Balance to their interconnection point is the idea. Radials are supposed not to radiate due to the balance of currents simultaneously flowing away or toward their interconnection point. The unbalanced long wire is supposed to do the radiation.

Balanced currents inside coax or in the wires of a balanced parallel wire feeder are not supposed to radiate either.

Place the feedpoint of your long wire antenna direxctly above the central connection of your radials. Place this feedpoint at some significant distance from your shack. Radiation loses about 22 db in the first wavelength of travel. Make the connection between your radio and the feedpoint with coax or parallel wire feedline.

This is how the radio broadcaster does it. But, he uses 120 1/4-wave radials under each tower, no long wire antennas which don`t have the desired directional characteristics.

Best regards, Richard Harrison, KB5WZI

Bill Nelson wrote:
"The tower would also be grounded properly and there would be a ground window in the equipment building."

Radio and tower suppliers have sample specifications. These mirror each other. Many land-mobile users build to these specs. Heft of the tower is based on wind load fears. But nearly all specify a ground rod for each tower leg each connected by a heavy copper cable. A similar copper cable is usually specified to run the length of the tower. I believe the tower-long cable is superfluous, but advise sticking with the specs. As the Russians say, "The salient nail gets driven down".

Best regards, Richard Harrison, KB5WZI

I am no EE and new to AR. In looking back I see the mere mention of those two terms brings howls and jeers like nothing I have ever seen on any board in my life. So I decided to check around. Fractal? The guy that invented it is (or was anyway) a professor at Boston U, I see hits relating to research at UCLA, Yale etc etc. People are getting degrees based on papers they wrote on fractal. And yet I see the shit that flies back and forth here..... And then EH. Never heard of it myself, I go to the site, and this fellow has a number of seemingly very satisfied users, well documented.
So what gives here?
Are Hams that closed minded and unprofessional as to summarily drum out anyone with a new idea they dont quite understand? Maybe I should search for another hobby rather than associate with such folks? Or is there something I am missing?
thank you for any insight to this question.

4181. Questions on EZNEC and TLA

Newsgroup: rec.radio.amateur.antenna
Date: 2002-08-30 16:00:43 UTC
From: Floyd Sense <sentek@sprintmail.com>
Message-ID: <LEMb9.7719$%D6.707580@newsread1.prod.itd.earthlink.net>
Source record: 135523

The last time I went through this, I just used my Autek analyzer, HP calculator and a couple of formulas from the ARRL Antenna Handbook. All went well and the antenna worked as it should. Now, with more time on my hands, I'm using EZNEC and TLA, and I'm not sure it's any easier! Here's a simple antenna problem I want to solve:

The antenna in question is a 1/4 wavelength vertical for 40 meters, with two quarter wave radials (perfectly horizontal), with the base of the vertical and the radials at 15 feet above ground. I used EZNEC to analyze the situation, and find that the feedpoint impedance is 26 ohms at resonance. So far so good, but it appears that using the EZNEC 3.0 I can't save this antenna design for later use - that requires EZNEC Pro - is that correct? If so, how are you EZNEC users saving your designs? I understand that I can build a file with the wire definitions and maybe that's how users do it?

Next, I want to use a coax stub (shunt connected) near the feedpoint to effect a match to 50 ohm coax (stub of same coax). Is there anyway using EZNEC to determine the stub length and distance from feedpoint? I know about the transmission line stuff in EZNEC, but it isn't clear to me whether this can be of any use in this case.

Last, I have the 18th edition of the ARRL Antenna Book, and the section on stubs talks about using the TLA program on the accompanying diskette to determine stub length and position. So, I installed the TLA program and read the descriptive text, but it's not clear how one would use it for this purpose.

This is an exercise in using the tools - please don't tell me why stub matching is no good or that the antenna would be better with 120 radials! Any other ideas or advice would be greatly appreciated.

Oh I am not disputing the fact that certain people seem a little 'cracked'
:)
I am interested in the technology, not so much the inventor. Do these
things not work?
If they dont work, why are people able to write dissertations about them
that say they do, and getting a degree for the effort? There is a paradox
here I dont understand.

Source record: 135529

In the main EZNEC window, you'll see a row of buttons. The second one down is labeled "Save". Clicking this will enable you to save a description (antenna model). You'll also find a Save As selection in the File menu, which does the same thing.

I strongly suggest that you, and other new users, read the Getting Started section of the manual. (The manual is accessed by clicking Help near the top of the main windows, then Contents.) It will direct you to the Test Drive, which leads you through the modeling of some simple antennas. One of the things you do along the way is save a description for later use.

You can add a stub to your model using EZNEC, but only on wires and not on a coax transmission line. EZNEC can't help you much with the matching problem -- for that you'll have to use TLA, WinSMITH, or a similar program.

Hopefully someone else will be able to help you with TLA.

Is your antenna resonant to the frequency of light? If not, I
expect it radiates photons very poorly.

WavyDave,
It's a lot like 'perpetual motion', some of the
theory behind both 'sounds' very convincing, but
when you dig a little deeper, you find a flaw. The
'flaw' with 'fractal' antennas is that there is no
particular benefit from using a fractal 'shape'. A
random 'shape' has been proven to do at ~least~ as
well, if not have better performance.
Exploring 'fractal' antenna properties is a valid
subject for leading to a degree, no matter is the
antenna works, or not. It merely shows that a person
is able to think and reason. Mercy! If you take a look
at some of the other subjects used to get a degree, a
'fractal' antenna isn't even the match that lights the
candle.
Perhaps the primary reason for the reaction that these
'fractal' antenna thingy's got the reaction they did is
the the person/personality/behavior of the person making
their 'discovery'. That is a whole different subject and
not really worth going into.
'Doc

Seems like I remember reading in one of Asimov's books while in high school
that light is the only 'energy' that has mass (photons) and yet behaves as
though it doesn't.

Thanks for the prompt reply, Roy. Well, you'll be surprised to learn that I did read your help document from front to back and memorized large portions of it. What I read in the section on "Save Description As" was this:

Save Description As - Allows you to save the current antenna description (model) as a file. [EZNEC pro only]: To save a file in NEC format, include the extension .NEC with the file name.

With the wrong pair of glasses on, this came through as saying that one could use this function only with EZNEC pro. Now that I can see all the punctuation, I read it differently. At any rate, changes I made to the model were not preserved in the save. Upon closer inspection, I find a file called "a.EZ" with my model data. When you do a File / Save Description As, the current file name is inserted and selected. Apparently, I accidentally depressed the "a" key just before I hit the Save button and didn't catch the fact that the file was saved as "a.EZ". Sometimes being a touch-typist is a liability. Sorry to have bothered you with such trivia.

Every time you transmit. Radiated RF *IS* photons.
You just can't see them.

The G5RV is resonant somewhere on 75m-80m but the feedpoint impedance
at the coax/twinlead junction is around ten ohms. That's not "highly
reactive" even though the 50 ohm SWR is 5:1. The load doesn't have to
be "highly reactive" for your Acom 2000A not to like it. Just because
something shows "a considerable SWR" doesn't mean it is not resonant.
Please don't confuse SWR with reactance. If your antenna is resonant
with a one ohm feedpoint resistance, the 50 ohm SWR will be 50:1 at
resonance.

Herb:

One of the replies said seal it up and no moisture will get in. This is true if you are in the desert, but everywhere else, the stuff tends to 'breathe' with changes in atmospheric pressure, and condensation forms in the relatively cooler earth. Unless you are in a swamp, some drain provision at the lowest point will eliminate standing water and eventual destruction of the coax. Keeping the drain hole open is another problem that I'll leave that to your imagination, but if you have vegetation with roots around the area, it will find the hole due to the tiny increase in moisture.

And, whatever size pipe or conduit you were considering using, double it (area, not diameter). I know of no one who regrets that. I know a lot of people who regret not doing that, including yours truly. There will always be another project or two requiring another cable or 3.

On Fri, 30 Aug 2002 16:00:43 GMT, "Floyd Sense" <sentek@sprintmail.com> wrote:

|The last time I went through this, I just used my Autek analyzer, HP
|calculator and a couple of formulas from the ARRL Antenna Handbook. All
|went well and the antenna worked as it should. Now, with more time on my
|hands, I'm using EZNEC and TLA, and I'm not sure it's any easier! Here's a
|simple antenna problem I want to solve:
|
|The antenna in question is a 1/4 wavelength vertical for 40 meters, with two
|quarter wave radials (perfectly horizontal), with the base of the vertical
|and the radials at 15 feet above ground. I used EZNEC to analyze the
|situation, and find that the feedpoint impedance is 26 ohms at resonance.
|So far so good, but it appears that using the EZNEC 3.0 I can't save this
|antenna design for later use - that requires EZNEC Pro - is that correct?
|If so, how are you EZNEC users saving your designs? I understand that I can
|build a file with the wire definitions and maybe that's how users do it?
|
|Next, I want to use a coax stub (shunt connected) near the feedpoint to
|effect a match to 50 ohm coax (stub of same coax). Is there anyway using
|EZNEC to determine the stub length and distance from feedpoint? I know
|about the transmission line stuff in EZNEC, but it isn't clear to me whether
|this can be of any use in this case.
|
|Last, I have the 18th edition of the ARRL Antenna Book, and the section on
|stubs talks about using the TLA program on the accompanying diskette to
|determine stub length and position. So, I installed the TLA program and
|read the descriptive text, but it's not clear how one would use it for this
|purpose.
|
|This is an exercise in using the tools - please don't tell me why stub
|matching is no good or that the antenna would be better with 120 radials!
|Any other ideas or advice would be greatly appreciated.

As you've been advised elsewhere, you can save the design in EZNEC. If you want to design your stub matching network at only one frequency, you could simply write down the feedpoint Z using the "Src Dat" button and look at the Impedance. If you want to do a frequency sweep then you can save the data to a file and see the impedance at each frequency.

You can then fiddle with this data in TLA. However, a better way is to download the Excel program XLZIZL.xls from www.qsl.net/ac6la and use it.

EZNEC saves a file named LastZ.txt which can be read directly by XLZIZL. The frequency and R jX then become inputs into the spreadsheet. Now you can use the program to build a matching network of up to 5 elements (or more with

intermediate steps), including transmission lines, and open and shorted stubs. The parameters for all of the common transmission line types are built in and these include the effects of loss.

The common Tee, Pi and L networks can be constructed automatically with the values optimized using the Excel solver or you can "tune" each component while watching the action on a Smith chart.

This is a wonderful program and to top it off, it's free.

It took me about 10 minutes to "build" a version of your antenna and match it.

I used #12 copper wire radiator 34.3', radials 35', RG-213 8.8' from feedpoint to shorted stub of length 30.5'.

A better solution (an exercise left for the reader) is to shorten the vertical element to make the feedpoint capacitive and use a shorted stub across the feed.

>... two terms brings howls and jeers like nothing I have ever seen.<

From a technical standpoint, there's really no comparison between fractal loading and EH antennas. In all fairness, fractal loading actually works (although, arguably, not as well as other solutions) and is being studied and reported upon in various forums including the IEEE. The flap on this newsgroup about fractals was probably more personality centered--kinda like witnessing a Tanya Harding vs Paula Jones WWF smackdown.

The EH, on the other hand, appears to be more in the carny catagory ("Heap Big Smoke and No Fire" if you have roots in the 50's). If you go back to the Miltonian era, the supporting literature reads like "Mrs. Malaprop Does Physics". EH proponents are religious in their zeal. "Blessed are the Believers", they whail. Meanwhile, others counter, "No, blessed are the Wee Beavers"! The Wee Beavers, of course, are the ones who actually took time in EE101 to study and comprehend what ole J.C.Maxwell was really trying to say.

Exactly. The electrical code recognizes this in requiring
conductors in buried conduit to meet the same standards as
conductors buried in the earth.

Where I live is classifed as "mountain desert" (less than 12in of
moisture per year, relative humidity seldom as high as 20% in the
daytime and often under 30% in the cool of night) but conduit still
fills with water. I once put air pressure into a friend's pipe that
he "knew" was dry, and blew out a gallon or two of water.

Bury at least 18in deep and most roots won't bother you. Put a
large area of gravel under/around the drain hole and consider using
a "automatic drain" intended for sprinkler systems. That way you
can pressurize the pipe if need be, plus it prevents all the
critters, dirt, etc. or most of everything from using that opening
to get into your pipe.

> And, whatever size pipe or conduit you were considering using, double it
> (area, not diameter). I know of no one who regrets that. I know a lot of

Yup. And once you are _certain_ the size is big enough, double it
one more time. If that isn't practical (already running a 4" ...)
then run two pipes instead of one. While the hole is open, do it.

Hi Rick--

Could you cite a reference which shows, for example, that in a confined form factor, fractal loading--that is the best fractal used-- is no better than other methods?

I am not familiar with said reference; I would also like to know how 'better' is defined.

All the unbiased runs I have seen on our fractal GO (genetic optimizer) FRAGO cluster start with a 'seed' of conventional loading methods--such as meander line loading (MLA's); 'T's; serpentine, and so on, and then iterate to better gains and bandwidths with more complex structure--which end up being fractal in shape. These runs do not in any way bias towards fractals: indeed, many of the early populations are conventional variants, superseded in the figure of merit by more complex, fractal forms. If they were better, or even the same, they would not be superseded, but make it to the final, 'convergent' generation.

One should note that this inherent growth to complexity of structure for optimized antennae was first shown 17 years ago in Landstorfer and Sacher (Optimization of Wire Antennas, Wiley, 1985) using more modest optimization methods and less exhaustive searches.

This FRAGO cluster now does over 30 NEC runs per minute in some simulations, and will surpass 1.5 million sims per month(!) in September. It typically does what a, say, 433 MHz, PC could do in year with a conventional GA in about a week. (I say this to indicate what platform I used the last time we met and to benchmark the progress of the optimization technology--which you appear to be unaware, or unfamilar with). In fact, it is now approaching the benchmark where the TOTAL number of publicly report antenna simulation runs EVER will be exceeded by it sometime in the Fall.

I'm not sure of the relevancy of taking, say, a Koch iteration 3 fractal and comparing it to some other loading method. It works fine in some cases, but is hardly the best in most cases--by a long shot.

I suspect the problem is that there are really only a small number of conventional loading geometries and methods, and as such, one hears 'fractal' and takes AN example as the indicator of all fractal possibilities. Why? I do not understand the scientific basis for such thoughts. It was neither stated nor directly inferential from anything I have written. The fractal geometry set is very, very large: the problem is finding what works best in a practical way. And, of course, what works better.

We are now long, long past the heuristic stage in fractal element antennas (the field is now 14 years old; it seems like yesterday to me!) So perhaps you are under some dated pre-conception? Or am I unaware of some hot, new result?

As I prepare a MS on these and other results, I would kindly be grateful if you could enlighten me. This post and query is informational with no sarcasm; if you speak from knowledge, as you allude to some discussion of s small team of IEEE representatives, then present it please. E-mail is fine.

That will depend on the GP/counterpoise used and the width of the monopole.
But I suspect you are searching for (about) 37 ohms, which is the real
impedance of a thin monopole on infinite ground.

We might as well forget it Cecil - it seems to be hopeless. Some people seem to think that 'photon' theory suddenly stops working at some arbitrary wavelength just below infrared. The fact that someone is now applying resonant wires (nano-antennas) to light (as posted at the start of this thread)... ...well, I guess that some people just aren't capable of making the mental leap and seeing the obvious.

And it's too bad that the 'interesting news' part of the posting ("...negative refractive index...", "...negative permeability and permittivity...") is ignored in favour of latching on to some detail. It's a bit like commenting on the news announcer's tie colour while WWIII is breaking out. This new technology (assuming that it is true) will stretch a few cherished rules regarding antenna theory. It will also keep Moore's Law going strong right down to individual atoms. It's big news.

Hi Jeff,

Take a deep breath, let the blood pulse slower and take note of one,
isolated but compelling observation made by the EE Times
"Now all the researchers have to do is build it."

The nano construction details are truly trivial. The nano factories
can build these like weaving carpet. If validation comes; then it
will be here for christmas. If they still have this on the launch pad
in next January....

It will be more like the long (mostly boring) history of the "LASER" (the quotes are for Dr. Evil :-)).

This new concept will be a technology in search of applications for at least 5 years. The chip makers will be happy to have it on the shelf for when they reach the point where they need it and have all the other necessary bits in place.

(Was it ?) Arthur C. Clark (that) said that everyone always optimistically overestimates human progress and change in the short term, and always massively underestimates human progress and change in the long term.

WASHINGTON (Reuters) - Experiments on a newly created composite material
have shown that it bends microwaves passing through it in a direction
that seems to defy the laws of physics, scientists said on Thursday, in
a discovery that could help in making more advanced lenses and
antennas.

The composite, made of fiberglass and copper, caused microwaves shot
through it to bend in an opposite direction than the laws of physics
predict, making it the first material to have a ``negative index of
refraction,'' physicists said in a study appearing in the journal
Science.

Electromagnetic radiation -- such as light and microwaves -- passing
through ordinary materials is deflected in the same direction, giving
those materials a ``positive index of refraction,'' they said. An
example is the way light bends when it passes from air to water.

The composite could be useful in developing better antennas and other
technology for the cellular communications industry, said physicist
Sheldon Schultz, who created the material along with colleagues David
Smith and Richard Shelby at the University of California at San Diego.

Although the composite cannot focus visible light, Schultz said he
hopes
that obstacle can be overcome in the future.

Physicist John Pendry of London's Imperial College has said that a
material with a ``negative refraction'' would make possible the
construction of a lens capable of focusing light to limits not
currently
achievable.

I have for sale 1 full size "HY-Gain" beam 10 meters. fully assembled
for your inspection. 13' Boom and longest element is 22' $100.00 I also
have a steel tower totaling 25'. this is in 3 sections 1 10 foot st8 and 1
5foot st8 and 1 10 foot top section. I don't not have a rotator. $50.00.
pickup only from Nashua,NewHampshire. I am selling these because they are to
big for my new QTH. This beam has spent a large portion of its life in
storage. 73's Jeff AA1GR

4216. B'nut HF5B beam - minimum distance from metalwork?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-08-31 13:15:38 UTC
From: MW0CDO <gw7lhi@hotmail.com>
Message-ID: <akqfhn$1jo8l8$1@ID-117699.news.dfncis.de>
Source record: 135557

Hi all.

I've recently installed a Butternut HF5B "Butterfly" beam.

It's boom is up around 30ft AGL.

Does anyone have actual practical experience of the minimum distance required from the antenna to nearby metal structures to avoid coupling or detuning issues?

Am I correct in assuming 1/2 wavelength clearance as a minimum?

The reasons for asking as follows:

1) I guyed the support mast with 2mm diameter multistranded steel hawsers, which are attached about 6 feet (2m) below the boom. The 3 guys are at roughly 45 degrees to the mast.

2) I have a Butternut HF6v vertical located about 10 feet (3 m) from the support mast.

3) Neighbour has a large (18ft x 15ft or 6m x 5m) metal clad (sides and roof) outbuilding in his yard... the vertical is around 7 ft (2m) from one side of it, and the beam is around 20 feet (7m) from it.

I note a significant change in SWR when rotating the HF5B beam. Laying the vertical on the ground affects the amount of change in SWR as the antenna is rotated on some bands. on other bands there isn't much difference with or without the vertical in place.

I cannot do anything about the metal clad building next door, but I can move the vertical and replace the guys with polypropylene rope.

I haven't been able to release the metal guys to check for any difference yet, because of winds at the moment.

Despite all of the above, the antenna works well compared to the vertical... and the vertical also works well here, very wet ground and about 400 yards from the sea shore.
The vertical is most definitely influenced by the building next door.. the SWR will alter as wind causes the top of the antenna to move nearer/further away from it.

My neighbour tells me that he does intend to remove the steel cladding from the outbuilding at some point.. still waiting after almost 6 years, but he's a great neighbour so don't want to complain, they don't say anything about the antenna farm in my yard! :-)

I suppose I could move the beam to the house end of my lot, but I don't really want to do this in case it provokes RFI problems etc.

Any thoughts on the above would be appreciated.

Paul MW0CDO.

Thanks, Wes. I'll get the program and give it a try. A shorted stub would probably give me less problem over the long haul than an open one anyway. For this particular antenna, it appears that an even better solution is to just slope the two radials down towards the ground, thus raising the feedpoint impedance to around 50 ohms.

Can I put two or more portable J-Pole antennas (made of twinlead or ladderline) into one PVC pipe, attach them to the same coax feedline and get a wide-band VHF antenna that will cover say from 144 MHz-165 MHz?

My inclination would be to just sandwich them together.

Chip,

Can you site a reference that shows, for a fixed volume, fixed total wire length and/or fixed resonant frequency, that fractal loading is the best geometry or even better than classic geometries such as a normal mode helix? Most, if not all of the articles discussing fractal antennas don't even

bother to compare the fractal geometry with other geometries

The fact of the matter is that for the electrically small resonant monopole like antenna, the height relative to the resonant wavelength primarily defines the resonant properties of the antenna (resonant resistance and bandwidth). Geometry is really only significant in its relation to how much total wire length is required to achieve resonance at a particular frequency. From that perspective, the self similar fractal geometry is inherently ineffective relative to simple meander line or normal mode helix antennas.

For a height of 6 cm, and a width 3 cm by 3 cm, and a fixed resonant frequency of 350 MHz, can your GO come up with the "best fractal geometry"? I'd like to see it and then compare it to some classic geometries.

Most paints won't destroy an antenna's ability to function. However, it may lower the beam's resonant frequnecies a little due to dielectric loading. If you use a caustic solution to prep the aluminum, however, that treatment could create a corrosion problem.

Rick-

Kindly read my posts; I said I was preparing a MS, and asked you to provide references for the assertions you have made. In other words, we are quite in accord on this issue.

In addition, Steve Best has been asked to publicly debate fractal antennas, and without an answer yet from him, it makes it somewhat challenging to publish a result if it is intended to be published as part of a debate proceedings. I, for one, would like closure. I also want it clear that as an ethical scientist, I gave a colleague the opportunity to respond in a means defined within the purview of scientific dissemination.

You go on the false premise that I have either something to hide, or am not honest. Neither is correct Rick. Please: as your colleague, kindly provide me the info I requested to enlighten your comments.

With Many Thanks,

Chip N1IR

As best I can tell, the "cactus J-Pole" is a standard 2m/70cm J-Pole
out of pipe that looks like a cactus. I am talking about stacking
J-Poles to broaden the 2m part to 144-165 and I don't much care about
the 70cm part (at present).

I don't think I can just add a third (shorter) branch to the standard
cactus to get 156-65 MHz, either. The stub would be too long. It
would require a second stub. Better just to stack two of them, if it
works.

Or, you could use the twin-lead as twin vertical dipoles on a single feedline,
one side cut for 2 meters, the other for the marine band or whatever you're
trying to hit.

4234. Dr. Kabbary's New EM Equations

Newsgroup: rec.radio.amateur.antenna
Date: 2002-08-31 22:25:36 UTC
From: Mont O'Leary <k0ycn@arrl.net>
Message-ID: <akrg5j$di4$1@news.chatlink.com>
Source record: 135475

Current issue of AntennaX has an article by a Dr. Kabbary which purports to show that Ampere had it wrong when he determined that conduction current caused the magnetic field. This guy claims that, even with direct current, magnetic fields are entirely caused by displacement current. Thus Maxwell's fourth equation is wrong. See http://www.antennex.com/shack/Sep02/em.html for details. Comments?

Hi Mont,

It is incredibly difficult to get beyond the paragraph sized sentences
that wander the intellectual dustheap in search of a jewel:

"Also to get the correct antenna theory rather than the present
antenna theory which is full of the well known many
approximations, assumptions and the unknown near field mechanism
of field reaction of building wave propagation or power radiation,
only the assumed far field, and its magnetic vector potential
related to the assumed sinusoidal (of no proof) current
distribution on the antenna elements, using moment methods and
mode theory; both full of the severe approximations of the phase
relationship in both macro and the neglected microscopic level,
this microscopic level in which field reactions occurs."

The baloney only gets thicker wading further into this drek.

Source record: 135478

HI folks,

I live in an inner city townhouse, two story, building's total length around 108 feet. Once the roof tower is installed for the 2 meter vertical I"ll have enough room to get a 75 meter dipole up easily I'm certain. However I'm curious about a couple of things.

I bought some regular 14ga 2 conductor wire for another job at Lowes a few months ago and have about 150ft of it left. TO my way of thinking this should not exhibit any strange characteristics when fed as a regular center fed dipole.

STill debating whether I should go to the expense of a commercially made balun (probably wouldn't hurt anything and might help with rf issues0 but looking for input from those who've been able to do a little more playing with this stuff.

tHis antenna would be basically a flattop with the ends drooping slightly but secured by ropes to not be in physical contact with the building. Any thoughts anyone? I've about a week before I get my climber up to do the work so want to do it right once and then only have to send somebody up for periodic maintenance as I don't climb anymore.

Hi All,

These two links offer what I have been seeing demanded by others: the consideration of a novel idea that could revolutionize antennas.

True to form, those whose stentorian calls for a new order, only pound the drum for a new order when their favorite design appeared to be ignored (call it eh/cfa/fractal/loops on a stick/what-have-you). When it comes to real news with real content by real scientists - silence and total indifference from those same proud trailblazing experimenters. reminds me of those once-in-a-lifetime queries (see sillyWilly or whatever he called himself) posted here about the miracles of fractals (you know, those folks who appear out of nowhere and pine away about the poor treatment afforded to the pioneers who struggle to educate us in the ways of these new physiks). Strange how they appear in concert with the maligned and offended innocent not far behind who bravely steps up to reclaim dignity and to present new "findings" (which turns out to be long on claim and short on content - still). The strange part (as some have already second guessed) is how these "seemingly" chance postings precede those announcements. Not so strange is their total abandonment of the topic once the "star" comes on stage for a performance (with trained GO chimps?). Pathetic as a

keyword still seems operative.

I found W.G Ewald's link to be far more productive, leading to actual details of the experiment and its results by Sheldon Schultz. It also revealed the actual photograph of the artificial dielectric constructed to exhibit a negative refraction. Jeff's link to Shalaev reveals a bibliography and speaking tour that easily eclipses the shallow psuedo-academic nonsense offered by the fractal community.

The body of work exposed by these two links, and the pages they link to in turn, reveal a considerable effort of thought and basic study so often discarded by our wanabee nobel laureates who would rather tell of how they sold matches on snow covered street corners rather than be traduced by the smarmy intellectuals who pooh-poohed (what cloying pathos) their ideas.

I can't say that I am convinced of these revelations, but they do offer more data than the previous 6 years of fractal/cfa/eh babble combined.

I'm an Asst. Manager for RS & if you frequent your local RS you know who the people are & who to avoid. As far as pushing cell phones goes we are under siege by our higher up's to push this stuff. Personally, if I see someone with a cell phone I don't even bother to ask I just get you what you need & get you on your way as quickly as possible. I still earn plenty of commission but after working with people directly for over 15 years (Previous Job) you can tell who might be interested & the person who knows what they want. I agree w/the other RS employee on this one, if you don't like being jumped on about wireless & satellite then take your business elsewhere. You have the right to tell an RS employee before he/she opens their mouth that you don't want to be offered a great deal & I'm sure they will back off. As far as product pricing goes, WE DO NOT make up the prices so don't bitch at us, these prices are set at the main office in Ft Worth and we have NO control over the cost of products. In fact we have no control over a lot of things and I myself would appreciate it if customers stop complaining to me & take to Ft.Worth 1-800-843-7422 or 1-800-THE SHACK if that's easier to remember.

Haven`t looked this up to check, but I seem to remember it was Ampere who said: "The induced voltage is proportional to minus d phi / dt".

The Faraday screen proves coupling relies on the magnetic field when reducing the capacitive field to zero. Coupling loss is negligible using the Faraday screen. Nearly every AM broadcast station uses a Faraday screen to reduce coupling harmonics to the antenna.

My VHF/UHF antennas are on a separate 60' tower. At the top of the mast (75') is a 6 meter quad. In several tests I've found that the 2 meter and 6 meter antennas work best for local (100-300 miles) communications if I lower the tower so the antennas are at about 35'. At the lower height, I consistently get local signal reports of 10-15 db stronger signals than with the antennas at full height. However, for 2/6 meter DX it doesn't seem to make much difference.

A little strongly worded, but basically correct in a limited way.

It's not just about efficiency Rick; the bottom line is directivity;gain;form factor; multiband; broadband; frequency independence; and so on.

In other words, as it always has been: what problem are you trying to solve?

BTW, that's a serious offer on lunch. Malden has a decent Chinese buffet place.

The antenna height and lighting restriction depends not just on proximity to the airport. All airports have a "circuit" or route that aircraft follow as they approach and depart a given runway. It's like a big square with the runway forming one side of the square. If you are directly on the approach or departure path to a given runway, you will have much more stringent antenna restrictions than if you are well away from that path. Similarly if you are on the crosswind, base or downwind legs of the circuit the restrictions will be tight but not as bad as if you are on the approach/departure leg. Best way to tell is that if you have aircraft flying directly overhead, you are on the circuit path. Check with your aviation authority Transport Canada or FAA in the US.

4254. G5RV Feedline

Newsgroup: rec.radio.amateur.antenna
Date: 2002-09-01 16:34:43 UTC
From: SeaQuest <seaquest@canada.com>
Message-ID: <Dkrc9.232064$v53.12503647@news3.calgary.shaw.ca>
Source record: 135495

I've been reading tons about the G5RV as I am just about to build my first one. I can't get a straight answer on one thing. If I am building one from scratch and will naturally be using a tuner, would I be better off with a coax feedline to the ladder line matching section or would it be better to run the ladderline right into the shack to my tuner (which handles both coax or balanced line). If coax should I go with RG8 (50 ohm) or would I be better off with RG59 (75 ohom). I should add that the run from the antenna to the tuner is 70 feet.

Jim

4255. Re: G5RV Feedline

Source record: 135497

Jim,
If you want to make a "G5RV" antenna, you have to
use a coax feed line to the twin lead matching section.
If you use twin lead all the way to the radio, the
antenna is no longer a "G5RV". It would still work, it
just couldn't be called a 'G5RV'.

Hi All,

I was more struck by the publisher's comment preceding this piece:
"I have left Dr. Kabbary's words as he sent them to me, with only
minor edits for punctuation and spelling. ... We would not wish to
alter the intended thought by a revision of the language of
presentation. Dr. Kabbary promises that more will follow on this
subject. ï¿½ Jack L. Stone, Publisher"

Such delicacy, such diplomacy. All window dressing to a brass-nuckled
backhand in a velvet glove. T'is a pity that when these rash
experimenteurs are given their proscenium, the actors on that stage
start hawking peanuts, popcorn and crackerjacks. When the audience
stirs for the show to get on, the cast boo the audience. Then they
expect Oscars.

On the other hand, the audience is not prime cut either.

On such a slow weekend we have the announcement of two revolutionary
ideas. One is exemplified in this tedious recitation above that falls
into the canon of standard fractal-babble (the same nonsense is found
at all scales of examination). The other comes from real science that
has implications that impact us all.

What's the difference? The cfa/eh/fractal crowd (maybe a dozen all
told) need a new theory of physiks to explain their claims - oh, and
yes, to make some money along the way(marketing being fungible for
science in their minds). The negative refraction side of the aisle
have their claims supported by conventional physics applied in
non-conventional ways - and with demonstrated results against physical
models. Is that a yawn, or what?

The cfa/fractal/eh actors strut about the stage to an audience that jeers them to offset their loss in the price of admission. This has all the hallmarks of the fascination that flies have for shit. [well, as this is my second post I must have a particular taste for it too]

It is enough that the good Dr. mocks himself by his own words (a familiar characteristic) - why not participate in a thread of substance instead?

The standard G5RV works well on 75m, 40m, 20m, 12m, and fairly well on 15m.
If you want to use 30m, 17m, and 10m, it would be better to go with ladder-
line all the way to the shack. In fact, G5RV himself recommended the all
ladder-line approach. This is not to say that ladder-line will solve all
the matching problems however. You will probably still have some problems
to solve on some HF bands. The free demo version of EZNEC will tell you
all you need to know. Download from www.eznec.com

> predict, making it the first material to have a ``negative index of
> refraction,'' physicists said in a study appearing in the journal
> Science.

From the descriptions posted of the material, I am
reminded of microwave lenses made from closely
stacked-together waveguide sections. Because the
phase velocity of waves propagating through a waveguide
near cutoff is greater than the speed of light,
the artificial "dielectric" thus created exhibits an
apparent negative index of refraction. This material
seemly extends the idea to higher frequencies and to
metallic elements that can be randomly oriented and
still exhibit the required wave interactions.

Mine is only about 22 feet from the ground. I have 2 10' masts
strapped to the side of my house (it's a ranch house). The top of the
second mast is just above the top of the roof. I am currently using a
double zep antenna, which is basically two 5/8 antennas, center fed so
one whip goes up and one goes down, kind of like a sideways T. The top
whip is above the roof. The bottom whip is below the roof. I've also
used a 1/4 wave ground plane antenna at 15'. One time during a
contest, I thought I was using my 3 element yagi on the roof and it
turned out I forgot to move the antenna switch. I was actually using
the 1/4 GP antenna and was making contacts halfway across the country.

Just my $.02.

The Radio Shack Discone is probably the bottom of the barrel of Discones in my opinion. The hollow elements are crimped to the threaded stud that secures them and they are always loose. I have had 3 Radio Shack Discones at several locations and two elements fell off my oldest one. I had an early Diamond Discone which was very similar in construction but the element attachment was far superior. The other brands may cost a little more but you will have an antenna that will last longer.

> that's easier to remember.

Let's put it this way. Some years ago, I quit going to Radio Shack because Even if I wanted to buy a couple AA batteries, I would have to give my name, address, telephone address, and other stuff EVERY single time. If I bought something on a corp account, I had to sign something like six forms, and the transaction took what seemed like forever.

I started going again because they eliminated that stupid idea.

But I can assure you, if I get prodded to buy a cellular phone every time I walk in the store, I'll stop buying anything there again.

The corporate suits who run the show are seriously misinformed about the shopping public. They will turn away business for the sales push.

The really interesting thing is that after the big cell phone push, which will drive the non-cell seeking public away, which means that the store sales will become mostly cellular, the suits will be convinced that their idea was right, because nobody will be buying anything else by then.

Remember the old "Jump Frog, Jump joke?

- Mike KB3EIA -

>want to be offered a great deal & I'm sure they will back off.
True, and I've been known to do that. My main bitch with the RS
stores I've run across in some communities where an actual outlet for
electronics parts has gone the way of the dodo such as the store in
Burlington Iowa where I used to reside until last spring.

I'd go in there looking for something, say pl259 connectors, and since
I"m a blind man i have trouble finding stuff in all those bubble
packs. SO I ask the employee. I tell him/her/it with no knowledge of
electronics that I do not want the crimp on connectors. WHen I arrive
at the house ... you guessed it.

I don't carry a cell phone but often carry a dual band handheld
transceiver with me. i"m not interested in a cellular phone. WHen
I"m away from my desk, I"m away from my desk and don't want to be
bothered by a damned incessantly ringing telephone thankyaverrymuch.
Hence, no cell phone for this old grouch.

Last summer I called the local rs store in Burlington to find out if
they had any transfer grease. THe little girl didn't know what it was
but could sell me all sorts of lube. FInally I grabbed a friend and
we went to the store anyway, but no transfer grease.

My worst gripe with RS is paying cash for something adn just wanting
to getr my purchase and walk out the door. IT's something small, a
connector or a crimping tool and I've still got to go through the
"what's your name and address bull***. Since you don't send me a
printed catalog anymore why bother getting my name and address? I
don't want a cell phone for a penny and I don'twant to give you my
name and address because I bought $8 worth of small parts.

I usually tell the sales droid that I don't even own a freakin'
television so why the hell would I want a direct-tv dish?
TV is one of the reasons we feed our kids dope pushed on them by
psychiatrists. iF we shoved 'em away from the box and sent 'em out to
do some physical activity maybe they wouldn't need the dope pushers in
the white coats pushing ritalin on 'em.

My favorite "trick" when they get pushy about satellite dishes...

First, I ask all kinds of questions that I already know the answers to, like what if there's a tree in my yard? How long of a cable run can I use from the dish before the picture starts getting fuzzy? (I really like that one... most don't have a clue. The pic doesn't get fuzzy.) Various things like that. Make 'em work for it, tho I do sound interested.

Let 'em talk me into a receiver for the bedroom, too. Go to the counter, they're drooling over the sale. Get to the point where they ask me for the credit card, in case of "early termination fee" is needed. Then I tell 'em I don't have a credit card; I do cash only. You can actually see their face fall.

To be honest, I don't do this much (at all) at RS. (Circuit City is much more fun.) The only thing I get from them is TV masting, cause I have a bit of theirs already. (Doesn't match the stuff from local the hardware store.)

4277. What If You Could Tune Out Polarization Mis-Match?

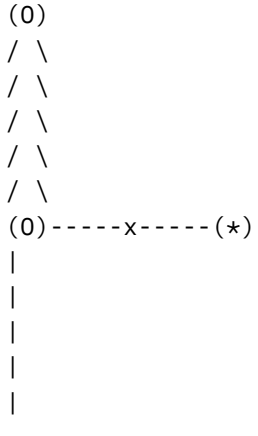
Newsgroup: rec.radio.amateur.antenna
Date: 2002-09-02 02:18:47 UTC
From: John Seney <wd1v@amsat.org>
Message-ID: <wd1v-A2A6A7.22184901092002@netnews.attbi.com>
Source record: 135419

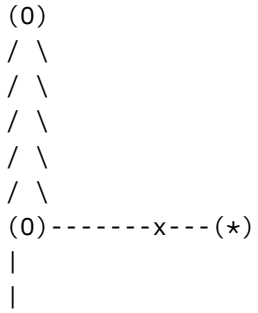
This is an idea for a new kind of HF antenna that might boost signal levels by as much as 10 dB or more.

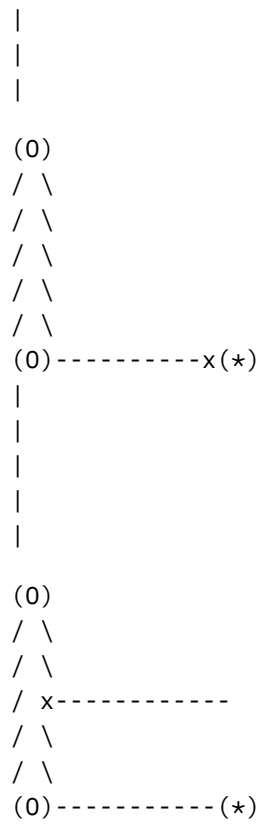
I should also relate that this reeks of "a little knowlege is a dangerous thing". I'm not an antenna designer. But maybe some of the gurus can set me straight if this concept stands a chance of being fun to play with and a useful enhancement for working HF.

The premise is based on the concept that as HF waves bounce off the ionosphere and bounce back to earth, the polarization of the wave changes. If the ionosphere is actively moving up and down, we may experience QSB (fading) due to polarization changes.

So this idea is to create a HF antenna that can change phase very quickly to reduce and perhaps eliminate the polarization mismatch. Consider a delta loop with a stepper motor and pulleys at each support. By advancing the motor (*), the feedline of the loop advances much like a clothesline carrys the wash out further for drying. The polarization changes accordingly - and given a fast enough motor, the potential exists to cancel the effect of non-complimentary polarization reception loss. (The effective gain by matching 2 yagis with the same polarization is dramatic. I have seen nulls approaching 40 dB when one yagi rotates 90 degrees from the other.)







Perhaps this won't work for reasons unseen.

Maybe it will work but there are better ways (electronic vs. mechanical)
ways of changing the polarization of an antenna?

I welcome your comments.

Since this is necessary only for receiving, the preferred method is to use crossed loops and a two channel receiver. You see, it only matters when the signal is within a few degrees of orthogonal to a particular antenna structure, and the rest of the angles are no more than a couple or 3 dB down. So you have a lot of margin to play with. You really should build a polarization interferometer with a angle and channel amplitude displays and watch the polarization wind around and the effects. The sharp null is usually from multipath, although it is occasionally from orthogonal polarization. Another approach to solving the problem is space diversity, either with a large aperture, multi element antenna like the CDAAs, or simply several dipoles spaced several wavelengths apart with appropriate combiners.

John Seney wrote:
"The premise is based on the concept that as HF waves bounce off the ionosphere and bounce back to earth, the polarization of the wave changes."

Diversity reception is an ancient technique to improve reliability and quality.
Space, frequency, and polarization diversity are used.

Frequency diversity works well almost anywhere in the spectrum but requires double the bandwidth for double diversity or triple the bandwidth for triple diversity reception. Regulators usually only allow special services including the military and common carriers to use the bandwidth required for frequency diversity transmission and reception.

Another technique is to select the upper or lower sideband of a double sideband transmission. This is often used in combination with the other means of diversity as there is usually not enough independence in the fading characteristics of related sidebands but sometimes interference is worse on one sideband than on the other.

Space diversity is available to everyone as it only requires multiple reception equipment.

Polarization diversity is little used at HF. That is evidence that it is not of much use where the polarization is scrambled by the ionosphere. Polarization diversity does find wide use in terrestrial microwave systems. It requires only one reflecter with cross-polarized feeds. One for each receiver.

Microwave space diversity requires at least two completely separate antennas in addition to two completely separate receivers, in most cases. Two separate antennas only get you a phased array. There is always some combination of signals received by antennas in a wild medium that will produce complete cancellation.

Switching diversity combiners are almost universal. The best receiver output is selected for utilization and the other or others are switched out of service. Long ago, multiple receivers were sometimes used and their AGC circuits were paralleled. A receiver with a hot siignal would turn down the gain on the poorer received signals. Noise output of this type of diversity reception wasn`t as good as a system which completely switched out the receivers with inferior signals, regardless of the type of diversity reception.

Short answer: Polarization diversity has been tried for HF and isn`t worth the effort.

Best regards, Richard Harrison, KB5WZI

Cut a hole through the wall, put in a piece of 4" electrical conduit,
sealed the conduit to the interior and exterior walls, ran the cables into
the house, plugged both ends of the conduit with plumbers putty, then
sealed both ends with plastic weather wrap and duct tape.

Mostly everything.

The original G5RV paper is available several places on the Internet, including here:

http://users.triconet.org/wesandlinda/g5rv.pdf

If you will look at it closely (sorry it's a scanned version of a Zerox copy) you can read: "Alternatively, open-wire feeder may be employed from the centre of the aerial right back to the transmitter output or ATU.

Figure 1 shows a "convenient length of open wire feeder" without any coax. The text above the figure includes "Here again, results are better with a tuned feeder....."

So, Varney (G5RV) in the original paper, seems to recommend a feed system *without* any coax. Does this not mean that a dipole fed without any coax can still be a "G5RV" or am I missing something?

Get a big masonry bit and go for it. Rat Shack sells a insert you can put in the hole. I just ran the cables though.. and plugged up the hole with some steel wool and then put duct tape over it. This will weatherproof it and it's easy to take off in case you ever need to make another cable run. If you used putty or something like that to plug up the hole it would be hard to remove should you ever need to run more cable.

John,
I think you're going at it from the wrong direction.
Instead of messing with the antenna to change the signal's
polarity, why not stabilize the ionosphere? Then you
wouldn't have to worry about the changing polarity.

Wes,
I think you're missing quite a bit. The horizontal
center fed doublet fed with some form of twin lead has
been around almost forever, Mr. Varney didn't invent it.
The antenna that Mr. Varney is given credit for uses a
twin lead 'matching transformer' as part of the antenna
system.

Hi Jim,

I've been reflecting on what you've posted, and it seems that the
phase velocity is one of those things I remember from elementary
physics classes, but only as a footnote condition of the math.

That is, the phase velocity is not the velocity of the wave itself,
but rather the difference between waves (or an interference pattern);
that is, something that is neither real nor contains any information.
As such it both presents a FTL condition and offers nothing
substantive.

The stumbling point for me is, as you've narrowed it down, with this
issue of speed and the discussion of speeding up transit time, the
inversion of the Doppler effect, and the near perfect focus ability.
Strange stuff to say the least, but at least no one claims that a
higher consciousness is required to follow the math.

Your observations of the physical construction being similar to
stacked waveguides is right on target to their presentation. They
offer a simpler condition, but still nothing more than the lumped
circuit equivalent of your description.

[snip]

Hey!

No problem...

Negative frequency [-f] is very similar to positive frequency, it just rotates in the opposite direction to positive frequency [+f]. Depending upon your co-ordinate system defintion... positive frequency rotates counterclockwise, while negative frequency rotates clockwise.

I have a neat homemade frequency generator here in my home lab with a frequency dial that begins with approximately -10kHz and passes through 0Hz and goes all the way up to +10kHz as you turn the dial. I use that generator for testing the filters that I design, build and use for separating positive from negative frequencies and vice-versa.

I kid you not!

Best,

Message-ID: <6820e6ce.0209020032.59f7e41f@posting.google.com>
Source record: 135439

I have just strung up 2 dipoles over the weekend. One for 40m and the other for 18m. I used a 10ft aluminium pole with a 1ft piece of plastic conduit tapered into the end. This was to prevent the dipole "seeing" the mast since it wouldn't tune at all just lashed to the mast. Just below each dipole centre I inserted a RF choke into each feedline (rg58) to prevent shield rediation. The choke was 4 turns of rg58 through a ferrite core (2.5cm diam) to produce a loop of about 10-12cm in diam. I had taken advice from an antenna book on doing this. The dipoles tuned OK but RX signal strengths are well well down (5-7 S-points) than on my mates 17m dipole just up the road in Perth. We compared signal strengths whilst on the phone. He has a FT-920 fed with rg58 (twice as much as my feed) and I have a TS-570. Interestingly my dipole is about 3x the height of his and orientated pretty much the same (N-S).

Just wondering if that RF choke is the cause or what else could be strangling it. Can anyone help out here before I have to pull the mast down.

Thanks alot in advance.

Jonathan

I use commercial plumbers putty with very good results. It's waterproof, not overly sticky and it only semi-hardens. I have opened my 4" pipe lead-through to add wires many times and the plumbers putty comes right out - kind of like a big donut. Little effort is needed, and there is no residue to scrape from the pipe or the cables.

How can steel wool be waterproof? I have seen it turn into a big lump of rust if even a little moisture gets on it.

First carry your rig over to your mates, set up a means to switch the
antenna between rigs and compare the S-meter readings.

Comparing s-meters on different rigs, on different antennas has too many
variables to begin to come to any conclusion. What is the difference in the
height of the antenna, orientation, etc.?

>Just wondering if that RF choke is the cause or what else could be
>strangling it.

HI Jonathan, The choke would almost certainly not be the problem. You say the dipole tunes ok, so I assume the swr is acceptable on transmit. If this is indeed the case, then the dipole is performing as it should.
Some possible reasons for different S meter readings than your mates: The S meters are not calibrated exactly to each other (almost a certainty). Your mate may have a preamp switched in the rx and you have an antenuator switched in. The dipoles may not be exactly pointed the same and you are getting some directional effects.
Try contacting several distant stations in various directions with your mate on the air at the same time. Ask the distant station to give both of you signal reports. That should tell you how the dipoles stack up.

Hi Group,

I use a old 5/8 CB ground plane with 20 feet of RG-58 as the line feed. The antenna is not very high. I use a MFJ tuner to operate on 20,17,15,12,10.

It works ok but not great. Would there be any advantage to putting the tuner at the antenna end? How about if I moved the antenna up to 40 feet and still used 58 cable and located the tuner at the antenna?

Does anyone make a remote tuner box which mounts at the antenna end?

Tnx, de KJ4UO

1. Take your radio to his location and compare it with his, using his antenna system, then have him bring his radio to your place and use your antennas for comparison. It may all end here. There can be lots of difference in receiver s-meters.

2. The RF choke you're using on the outer shield of the coax cannot affect what happens inside the coax where the signal travels. Removing it won't raise your recieved signal strength. UNLESS his sytem is using the coax outer shield as part of the antenna, for yours is not, with the choke in place. THAT may be the difference. Might be worth placing a choke in his feedline, same as yours, and comparing again. Or taking yours out. The outer shield does indeed often act as a part of the antenna when a balun or choke is not used.

3. Always suspect coax connector problems in such cases.

4. There are often working differences in antenna systems in different locations that are difficult or impossible to easily explain. First sort out that which can be easily explained, as above.

Hi Steve,
There are several ways it can be done.
If one is available, use a basement window. Cut a piece of plywood or plastic to fit the size of the window frame, +1/8" in height. Drill a line of holes horizontally across the piece. Put in more holes than you will need. The holes will be large enough so that when they are finished and you run the piece through a saw cutting it in half, going through the middle of the holes, they are the size of your coax when put together. Screw the lower piece into the window opening, after removing the window of course, lay your coax pieces into the half holes and then install the top half. Use your favorite sealant to seal the coax and a piece of wood /plastic to seal up the open holes for future use. When you move/sell you can put the original window back in.

If you do not care about leaving holes, use a rotary hammer drill. If you do not have one rent it and the bit. Drill through the concrete or block/brick and bring the coax in that way. Unless you are good at measuring get a bit long enough to go al the way through the wall you are drilling. Again, use your favorite sealant.

Wood trim areas around windows may also be used. These may also be patched and painted after removal to hide them on the outside but are hard to hide on the inside. You may want to experiment.

Soffit areas can be used if you have a closet or other way to introduce the coax into the hose without getting your mate in a frenzy. Cut a rectangle hole in the soffit to fit a soffit vent screen, buy one at the hardware store. Run the coax into the house and bring it down through a closet ceiling. Make a hole or an access door with trim so it looks good later.

There are just about as many ways to do this as there are hams. These are some of the ways I have used in the past.
I hope this helps.

I was impressed by a demonstration of an ordinary HF mobile unit (no big amplifier) one evening by one of our radio club members. He is a native of Malta and his brother who is also a ham still lives there.

The local ham picked up the microphone on his mobile rig, gave a call, and his brother on Malta immediately responded loudly and clearly. It was very early in the morning on Malta.

The local ham was using a short vertical whip on his mobile. Low verticles work better than low horizontals for DX.

Hi Steve,
One of my basement windows is a small sliding type. A small wood frame with a piece of plexiglass fits in the opening for the window. (One of the sections of the window is moved over by this frame, but I jammed some foam insulation between the sections to keep bugs and cold air out). A bulkhead coax connector is inserted in a hole in the plexiglass. A ground wire is connected to the outside coax connector using a hose clamp. There's also a big screw going through the plexiglass for the ground wire from the rig. It ain't pretty but it works. 73,

[snip]

Zero? Great!

So then f = 0.0001 Hz is still OK, and...

...so is f = 10^-20!

"Wow"... as the Engineer said to the Mathematician... "that's as good as
zero".

Now that we can use f = 10^-20 as a "good" frequency maybe we can get Cecil
and Steve to calculate some reflection mechanics for us at that frequency
using Smith Charts, etc...

I'd love to see the where the reflected power from a 50 Ohm load resistor at
the end of 100 feet of RG-93 fed by a 100 Watt 50 Ohm 10^-20 Hz transmitter
is dissipated.

The length of the matching section depends on the VF of the line
that is used. The length is 1/2 wavelength on the 20m design
frequency. The 300 ohm ladder-line that I use has a VF of about
0.8. My design frequency is 14.2 MHz. That gives a matching
section length of 27.7 ft.

Afraid not, Richard. At least not in the last half century. I only know one transmitter that uses a Faraday shield and it's for HF use. And yet almost every station has a Faraday shield somewhere in the station to prevent capacitive coupling.

I am really surprised that this topic appears to be giving heart burn to so many people. Peter is the only one that has given any indication of having an understanding. Old time DXers know; however, that the power in positive frequencies travels the short path to the distant end while the power in the negative frequencies traverses the long path. It is just the way DX IS!

Happy Labor Day to you as well.

Yuri, I have found that running my satellite rigs with both positive and negative frequencies allows me to change the "sense" of my circular polarization antennas without having to rewind them. I don't know why no one else hasn't thought of this neat set up.

For instance if I use positive frequencies with a clockwise polarization antenna I get regular clockwise polarization, then with negative frequencies applied to the same antenna I get counter-clockwise polarization. There are other amazing results from operating this way... for instance.

I find this useful for full duplex moon bounce where, as you know, the reflection off the moon reverses the circular polarization so that usually, to avoid polarization losses, one requires two circularly polarized antennas, one for transmit and one for receive.

My moon bounce set up just uses *one* circularly polarized antennna. I transmit on the positive frequencies and receive on the negative frequencies.

Of course the duplexing is easily accomplished without the use of hybrids, etc... by just using single sideband filters with the transition band at zero frequency. The upper side band filter then passes only the positive frequencies, from the transmitter, while the lower side band filter passes only the negative frequencies for the receiver.

I've been using this postive/negative set up for a few years now and I've almost reached DXCC on EME using it.

The EME DX hunting has kept me so busy that I just haven't had the time to write up an article on the technical details for QEX.

When I do, I'll be sure to let ya'll know...

Best,

There is one factor you're omitting. Hams by nature are exceptionally
tight with a buck. They may spend thousands of dollars for a rig, but
they'll also go from dealer to dealer to try and squeeze an extra five
bucks' discount out of them. They'll also do things like buy a rig from
a dealer, get it home and try it out, then ship it back to the dealer
and try to get a full refund out of it. HRO has moved to discourage
this by charging a restocking fee of something like 15% since they can't
resell the unit as new once it's been sold and opened.

This is one of the reasons why margins are so tight -- you have to cut
the price to the bare minimum in order to be able to stay in the market.

Just my two cents' worth.

4325. Aviation scanning on a CB Antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2002-09-02 16:08:49 UTC
From: Steve Danhof <stevedanhof@attbi.com>
Message-ID: <l2Mc9.172237$aA.34468@sccrnsc02>
Source record: 135467

I have a handheld Sportys SP200 Nav/Com than sends and receives between 118.000 MHz and 136.975 MHz and receives 137.000 MHz to 142.975 and 108.000 to 117.950 MHz.

I have a mobile Wilson 2000 CB antenna and some other base antenna at my house.

All I want to do is monitor these frequencies with the scan feature on my tranciever. I will not be transmitting at all while using these antennas.

Is this possible and safe for the radio?

Thanks for your help

Peter, K1PO wrote:
"I`d love to see where the reflected power from a 50 Ohm load resistor at the end of 100 feet of RG-93 fed by a 100 Watt 50 Ohm 10^-20 Hz transmitter is dissipated."

As Peter says, the frequency is as good as zero Hz. The coax is surely low in d-c resistance as compared with the 50-ohm load resistor.

The load resistor soon burns out and the resulting open circuit accepts no more power.
The transmitter is designed to deliver and dissipate internally the power associated with 100 watts. The load is only designed to take 50 watts I have assumed.

Best regards, Richard Harrison, KB5WZI

Wow!
Awesome dude!
Without trying to expose your patentable tings, I gather that LSB/USB filters are edge parked at 0 Heartz. I wish I had time to get to bounce the moon, I am still trying to recover for the teorethical beating in the contests I didn't go head to head with team Freaktall on 10m. I am trying now to concentrate on low bands before the Freaktalls get there. It could poison the low bands for all those guys with them stupid big antennas, forsquares etc.
You better get patents going because many scientwists are closing in with all them faster than light antennas, Freak-Fracs, EH?
Have Phun!

Fred, W8OY wrote:
"And yet almost every station has a Faraday shield somewhere in the station to prevent capacitive coupling."

Yes. That is what I meant to say. All medium wave broadcasters I`ve seen use the Faraday shield in the tower dog house where the transmission line is coupled to the antenna tower. It does double duty there. It grounds out harmonics and it grounds out lightning strokes.

Best regards, Richard Harrison, KB5WZI

4329. Antenna switch question

Newsgroup: rec.radio.amateur.antenna
Date: 2002-09-02 16:31:47 UTC
From: xrecho@eminem2000.com
Message-ID: <18d5aac7.0209020831.581e47dc@posting.google.com>
Source record: 135369

I have 3 antennae that I would like to connect to the rig for different frequencies, using a Diawa coax switch. The switch only switches the center conducter of the 3 coax lines, leaving the braid of all 3 antennae connected together. The center conducter is connected to the "right side" of the antennae so there is no problem with that.

If I switch to antenna #2, for example, I am feeding the "right side" of antenna #2, but also feeding the "left side" of antennae #1, #2, and #3. It would seem to me that I have the equivalent of a dipole with one short side and one extremely long side (unless I could disconnect the braided side of these antennae).

I asked one ham about this and he said the braid side (left side in this case) was connected to a common ground and would present no problem. I do not understand the logic in this, since "RF Ground" switches between the left side and right side 14,300,000 times per second on 20 meters. It would seem that the radio would see the right side of one antenna and the left side of all 3 antennae for as long as the coax was connected together. Can anyone explain this puzzlement? Thanks, Justin

The people who install satellite TV cables have a sealant that does not harden like putty. I imagine many hardware or perhaps electronic supply houses can identify the products.

Hi Steve--

I respect your opinion.

Of course, the situation is further exacerbated by the declining ham population; the (presumably) high unemployment rate of hams (who are disproportionately in the telecom/related industries), and the fact that most antenna companies that sell to hams aren't focused on hams to start with.

A major antenna company closed their NY state facility last month and many will post record losses for the year (my informed speculation). Also, I have never seen so many antenna engineers looking for jobs: decent, well-qualified folk with great backgrounds, and, unfortunately very few jobs to fill.

Tough times, indeed. Maybe we hams should break open our piggy banks:-)?

73,

I think you should do the whole tower, mast, rotating device...and the antenna.

In the military, a dusty gray, kind of a powder gray, between white and real gray was the color we used for sky camo. If you are going below the tree line....that is will the neighbors see trees in the background while looking at your antenna, use a camo combo of green, brown, and black, random sploches.

Krylon will detune a bit, but you can fix that.

Good luck!

KJ4UO,
Sure it would work 'better'. It would act
like an impedance matching device at the input
of the antenna (a gamma, etc.). does anyone
make a tuner specifically to do that? Not that
I'm aware of, but remote tuners such as the 'SGC's
would do it. Kinda expensive, not sure it would
be worth it...

> 73,
> Chip N1IR

See Chip (and supporters) you have just encapsulated in those few words the core of the problem, the reason for the disdain with which your technology is regarded in some quarters. I will explain.....

I am no Luddite believing that only a straight wire can radiate, or similar closed-minded soul. I am optomistic that all antenna theory is not yet known, and new discoveries await us. However, I have great difficulty picturing in my "mind's eye" as it were, the working of a fractal antenna. Simlarly the EH antenna seemed at first glance a flight of fancy. However, I and any one of my peers can go to various websites and find design information and explanation of the EH antenna so that we may better understand the thinking of its proponents. We can even build one from published design parameters. Not so fractal antennas. Anyone who attempts to spread a little understanding on this subject is met quickly with the sound of you firing a full broadside of potential litigation from every gun you can find.

My EH antenna did not work very well. I have theorised on a number of reasons why this may be, and why those "good" installation were so. By discussing them with the "inventers" and my peers, and probably having many of my theories debunked, we shall acheive a better understanding of this technology. Indeed, through theorising and the subsequent debate, even the inventors will come to better understand their own technology. Thus it may be that in a few years we are all using EH antennas, or it may not.

I would love to be able to try a similar exercise with fractal antennmas but I cannot. My antenna knowledge, despite being what many would call "advanced", does not allow me to see the concept behind the "specialness" of the fractal from an antenna loading point of view. Unfortunately, you closing of the "ham" page on your site (reason given is ridiculous, you need to cool the paranoia. If bin Laden wants one of you antennas he'd have got someone to steal one well before now) and your bullying of anyone who attempts open discussion of the technology means that I am likely to always remain ignorant on this subject.

Underneath the bloody-minded face you present the population of this NG, I am sure that there is a reasonable guy. Come on, as a scientist you know that any theory must stand up to peer scrutiny. Ignore the shouting Luddites

and let the more reasonable of your peers have an informed debate on the subject. Allow the information to be disseminated. Allow websites to publish non-commercial designs and critiques. Only in this way will the true value of "fractal" antenna technology become known.

Kind regards

Alec Wood M1BNK
Teesside UK.

Yes, it's possible. It's also safe for the radio. However the reception
would be better if you use some kind of VHF antenna instead of a CB whip.

Plastic -s usually better. Basements are dark enough to begin with....
I took out the double-pane, stationary section of my 2 piece sliding
glass window and built a double-pane *plastic* panel to replace it.
Not at all that difficult. (Then I used silicone glue to affix
a *third* plastic panel on the outside frame. It's 7703' (2345m)
here.) 'Tis easy to drill through for coax and rotator cables.
I used a hole saw for 2 runs of 3/4" hardline. I apply a bead of
"strippable" weather caulking around each cable/coax at the outer
plastic panel. (This was mentioned in another post here. What you're
lookin' for is, either Red Devil "Zip-A-Way", or DAP "Seal 'N Peel".)

On Mon, 02 Sep 2002 08:21:57 -0700, Dick Hughes
<rhughes33@cableone.net> wrote:

|I disagree Wes. Varney even states, "For installation in a very
|limited space, the dimensions of both the "flat-top" and the matching
|section can be divided by a factor of two to make the half-size G5RV,
|which is a very efficient antenna from 7 to 28 mhz." Therefore, a 51'
|flat-top is still a G5RV antenna. The "special" part of the G5RV
|design is the use a specific length of ladderline to serve as a
|matching transformer on 20-meters.
|
|Varney goes on to say, "In contradistinction to multiband antennas in
|general, the full size G5RV antenna was not designed as a half-wave
|dipole on the lowest frequency of operation, but as a 1 1/2 wave
|centre-fed long-wire antenna on 14mhz, where the 34ft (10.36m)
|open-wire matching section functions as a 1:1 impedance transformer,
|enabling the 75ohm twinlead or 50/80ohm coaxial cable feeder to "see"
|a close impedance match on that band with a consequently low vswr on
|the feeder. However,on all the other hf bands the function of this
|section is to act as a " make-up" section to accommodate that part of
|the standing-wave (current and voltage components) which, on certain
|of the operating frequencies, cannot be completely accommodated on the
|"flat-top" (or inverted-V)radiation portion."
|
|Dick - W6CCD

Reeling him in I reply:

Nope, you're reading a different paper than I am. The *original*
paper says no such thing.

And that "special" length of ladder as Varney himself says, "..in this
case, acts as a one-to-one impedance transformer..." Therefore, it
does *no* matching on 20 meters and contrary to what he claims, it
doesn't "make up" part of the antenna on other bands any more than the
200' of Heliax feeding my beam "makes up" part of the antenna.

Hello Alec,

Nice to hear from you.

I fear you are doing me a disservice: from 1995 to 1991(late) I published several ham articles, and had web-based construction instructions, available for hams.

That has changed since last Summer, as I do not wish to make any construction discussions available. I cannot vouch for the accuracy--indeed clearly , in many cases, inaccuracies-- of other such ham-based discussions.

Call me over-cautious if you wish: that's quite OK.

I request that you respect my wishes on this and kindly not make such requests of me or my affiliates. It will continue through the duration, regrettably.

And please do not make such false attributions: a quick e-mail or check of the records would have indicated the situation.

I thank you.

73,
Chip N1IR

Polarization selection is worth well at times on some bands. A Couple
of years ago I did some
experiments on 10 meters. I mounted a vertical dipole at the end of
the boom on my 3 element
beam. Mounting it at the end of the boom kept it away from the tower
somewhat. I used feed
lines of the proper length for each so that the vertical dipole and
driven element of the beam
were electrically at the same point. (zero distance between them)

In the shack I could then switch in various combinations of delay
lines so that I could get various
polarization's. Right hand circular, left hand circular, vertical,
horizontal or vertical and horizontal
in phase.

I kept a schedule with a friend in Northern Michigan from my qth in
south Florida. About an
1800 mile path. It was interesting to note that at times each
polarization had it's moment. Some
times right hand circular was best and switching to left hand would
drop the signal way down.
Other times the opposite would happen with left hand being dominant.
Other times vertical alone was the best and at times the horizontal
alone was best.

The polarization rotated rather fast. It would stay at one
polarization for only about 5 to 10
seconds. Then another combination would be best. You had to constantly
keep switching.

The fact that there was a marked difference between right hand and
left hand polarization made
it clear that the polarization was rotating and that the differences
were not just caused by multi
path propagation causing cancellations and re enforcement's. Although
some multipath may also
have been present.

There were times on the band when polarization seemed to be more stable and changing
antenna combinations didn't help much at all.

The best combination for overall signal stability when the polarization was changing rapidly was
the horizontal and vertical antennas in phase. This cost some overall gain but the signals were the
most stable with this combination and no switching was needed.

The station at the other end of the path was always using a large horizontal loop. (about 150
feet on each leg) We wanted to get a vertical antenna up at his end in addition to be able to try
combinations on both ends but the band closed down before we got to it.

By the way when I switched from horizontal to vertical polarization the path was not always the
same in both directions. It was kind of hard to tell as things changed rapidly but from what we
could determine some times when I received best with vertical polarization, he would receive
best when I transmitted horizontal polarization. Other times it was best both ways with the same
polarization.

We did try to make allowances for the difference in the difference in gain between the 3 element
beam (horizontal) and the vertical dipole. But the difference in signal strength at times was much
more the difference in gain of the vertical and horizontal antennas. At times his signal would be
say around S 7 on the vertical and unreadable on the beam and at times the opposite would
occur.

I had also hooked up two receivers running them both on common oscillators (vfo, hf and bfo)
so that the phase relationship would be constant with the two receivers. I connected one to each
antenna, horizontal and vertical. Watching the IF's with a two channel scope I could see the
phase change between the two signals.

I tried listening to the two phased locked receivers at the same time too. It was interesting to
watch how dramatic the change in signal levels between horizontal and vertical was at times.

On the lower bands it is a little more difficult to do the same experiments but it would be
interesting to try.

I also briefly tried an electronic switch, switching between vertical and horizontal rapidly with
one receiver. The thought was that the average signal level would be better. Switching speed
was cranked up to several KC, above the audible range, so as to be inaudible. Problem was
that the switch created inter mod.
Maybe someone has an idea for switching?

For what it's worth, one of my former compatriots at MFJ reported hams at Boxboro were spending like crazy this year. Amateur sales, which seems to enjoy a level of immunity from the general economy, appears to be experiencing what Alan Greenspan might term "a minor up-tick".

As the sunspot cycle heads for the locker room, I don't anticipate hot sales for HF antennas over the next five or six years, but sales for VHF and above should remain active. And, while the overall ham market will continue to shrink as active numbers decline, all those licensed boomers and yups are shipping the last kid off to college. Think of it! They, along with scads of marginally employed professionals from the technology sector, will have more spare time than ever to....do whatever they want (I don't know about you, but it was always lack of time and not the lack of money that kept me off the air).

Heck, even PCs aren't taking the huge bite out of expendable income they did five years ago. Many hams are keeping the rag-tag old 1.2-GHz Pentium III so they can spring for a DSP "dream rig" instead. With digital voice lurking around the corner (it's already driving VHF scanner entusiasts nuts on the public servce bands), the first significant mode shift since the '60s will soon be upon us. Imagine, thousands of servicable SSB and FM radios headed straight to the attic. What a beautiful sight!

It may not prove all that lucrative for the antenna guys, but it's sure gonna be fun to watch!

I would be concerned about loading coils or baluns that might be part any HF antenna. They may make tha antenna unusable at VHF, in which case you would be better of with just 3 or 4 feet of wire for the antenna. Or, you might try TV rabbit ears with a 300 to 75 ohm TV balun. BTW, I think 108 -118 is VOR, not voice.

Hey Rick--

Got a question for you; assume also of interest to others.

The main virtue of SSB as a voice mode is that it is not, per se, a 'matched filter' approach to rejection of unwanted signals and noise. Thus, we can all hear each other with the minor inconvenience of tuning properly, and rejecting some fidelity of the spoken word.

In DSP voice, you have a A/D/A matched filter, and the more you match, the tighter the rejection; higher S/N, and so on.

What happens in a ham 'contest', where one seeks to kick up the rejection, yet also has to deal with being able to get the message across. Do we all use a priori settings that are agreed upon before the contest?

I don' know anyone who has successfully demonstrated the efficacy of DSP voice in such situations, but would be fascinated to see who has. Basically it is very good in 'low probability of intercept', whereas we hams usually want a 'high probability of intercept'.

Perhaps you can enlighten?

Yeah, it's an *apparent* velocity. In the waveguides mentioned
above, it's what you would get if you multiplied the wavelength
observed inside the guide by the frequency of the exciting source.
Doesn't mean jack. The waves inside are just bouncing from
wall to wall rather than propagating through the guide in a
straight-through manner.

The lenses made from such structures can be analyzed as having
a refractive index less than 1.0 and exhibit the "opposite"
quality of a concave surface bringing a plane wave to a focal
point.

Mathematical reasoning *is* a higher consciousness. ;-)

> Your observations of the physical construction being similar to
> stacked waveguides is right on target to their presentation. They
> offer a simpler condition, but still nothing more than the lumped
> circuit equivalent of your description

My take on the development is that by embedding the very
small, wire structures in the dielectric they were able to

create a slow-wave medium that could be made to have a
wide range of group-delay and phase-delay characteristics.
Your drawing a parallel to lumped L-C networks (and I
would add coupled resonators) is particularly apt.

However, no physical laws appear to have been violated
in the process. Nor were any small animals harmed.

[snip]

Yep...

Hey, I always use the positive frequencies on long path and negative frequencies on short path.

Also I have found that when you work "split" using the positive-negative frequency set up you don't have to remember and control two different frequencies if you....

...Just call on the + freq and listen on the -freq.

Works great!

Of course my whole HF pos-neg transceiver is homebrew... Can't buy this stuff yet!

I use the PNP transistors in the positive frequency oscillators of the rig and the NPN transistors in the negative frequency oscillators. Potential users beware this idea is: Patent Pending, Copyright and Trademark. The schematics for the design have been kept in a wax sealed Mason Jar on Funk and Wagnal's front porch since Johhny Carson retired!

But... ahem... I think I've already told you guys too much...

I have been afraid to write up the "pos-neg" designs for QEX until my pending patents issue, just in case those greedy amateur equipment manufacturers try to steal my ideas.

Eat your heart out MFJ!

Best,

Where does this article refer to a "double the original" size of the g5rv? I see a reference where the feedline can be strapped for 160 meter operation, and a reference to a 1/2 size g5rv, but "double"?

Have a good day...

Gary, K4FMX wrote:
"Polarization selection is worth well at times on some bands."

Yes. It is used for diversity reception in the microwave bands because it`s cheaper to mount one dish with cross-feeds than two dishes as needed for space diversity. Space diversity is more common at microwaves than is polarization diversity despite its higher cost.

As far as I know, all commercial HF diversity is either space diversity or frequency diversity. This is cut and dried. The military used TDR`s in WW-2. Signal Corps rhombic kits (3 ea) were erected at two to ten wavelengths apart. More is better but 10 is good enough. Hammarlund Super Pro`s were the usual TDR receivers (3 ea), one connected to each antenna for each frequency being received. Multiple receiver triads were connected to the same antennas, one receiver triad for each frequency being received.

One antenna would suffice for frequency diversity in a single direction were frequency diversity the only mode in use. All three receivers tuned to different frequencies carrying the same signal could simply be connected to the same antenna.

An additional TDR receiver group of three antennas is required for each direction of reception as a rhombic has a very narrow beamwidth in most cases. Multiple groups of three receivers for each frequency in use can be used with each group of three antennas as above.

The TDR switching combiners used by military and commercial users automatically picked the strongest clean signal from the three (or two) available in a group, and switched it to the output terminals.

U.S. Commercial receiving stations usually also used Hammerlund SP-600 receivers and Crosby or Pioneer combiners, just like "government issue".

You may be able to find a surplus combiner of the old or a newer type. These switch almost imperceptibly.

Best regards, Richard Harrison, KB5WZI

A simple explanation is like the wiring to a light bulb, only one wire is switched. Because no current flows to the other antennas, none returns. Just like dancing it takes two to tango and two of the antennas have no partner...

From the height difference it appears that your antenna would have a lower elevation take-off angle than your mate's. What was the distance to the station that you were listening to? 5-7 S-poins, if correct, should be something like 30-40 dB, which is much more than the take-off angle effect, but anyway, just something that came to mind in additional to the other inputs you got.

> Sverre LA3ZA
[snip]

Hi Sverre! Yet another negative frequency enthusiast. And they say ham radio is dying! What?

Yes that's correct.

Of course you have to use power supplies which supply positrons to the negative rails and other supplies which supply electrons to the postitive rails, etc... those detailed technology issues should be obvious to anyone skilled in the art.

The real problem, and that's where the pending patents lie, is in the pole-zero arrangement for those filters...

For the positive frequency filters the poles are in the left half plane and for the negative filters the poles are in the right half plane. The trick is in the phase compensation required to keep those left half plane poles stable. And... you gotta make sure the power supply sequencing is such that the positive supplies come on before the negative supplies, etc...

Best,

Since when is a balanced line supposed to radiate?

The LADDER LINE IS A TRANSMISSION LINE. It is NOT PART OF A RADIATING STRUCTURE! It has no magical properties. Neither does a "G5RV" antenna. It's a frigging dipole for goodness sake. The antenna does not "fold into the transmission line". The transmission line does not "make up" part of the antenna. They have TWO SEPARATE FUNCTIONS. Put a battery-powered transmitter at the feedpoint and there will not be a dime's worth of difference in operation.

Varney is dead. I wish he would have taken his old wives with him.

This is definately my last response to this thread, tongue-in-cheek or otherwise.

He wrote quite extensively. For instance, in the ARRL Antenna Compendium,
Vol. 1, he wrote about the G5RV antenna. Speaking of the feeder length:
"A convenient length of open-wire feeder is 84 ft. ... This is not a rigid
feeder-length requirement, and almost any mechanically convenient length
may be used."

All true. But I did an experiment one time in which I tried varying the
length of the dipole in order to achieve resonance at different frequencies.
It was sort of like the Yo-Yo dipole except I had two pulleys at the
center of the antenna and a pulley at each end with a weight on each
end. I pulled on the feedline and the dipole shortened. At the same
time, the dipole "folded into the transmission line", i.e. part of the
dipole became parallel transmission line. I was sure surprised when that
antenna system didn't change resonance by very much. In lengthening the
feedline by the same amount that the antenna is shortened, the resonant
frequency didn't change by very much, certainly not nearly as much as
shortening a coax fed dipole.

>closing of the "ham" page on your site (reason given is ridiculous

Hi Alexander,

I'm not sure of the type of exercise you speak of. Construction? In
that regard, my site is not of any particular note:
http://www.qsl.net/kb7qhc/antenna/fractal/index.htm
My work simply explores the variety of shape, iteration, against two
simple criteria: how tall, how much wire. As noted by Steve Best, a
published fractal antenna designer, little research effort from the
run-of-the-mill fractal papers goes to the scientific standard of
establishing a control. My analysis at my pages does only that and
nothing more.

You speak of "specialness" - there is none. [Unless you misspelled
speciousness for which this field is notable.] All characteristics
conform to the usual expectations - no surprise either. Differences?
Yes, certainly. Significant? Perhaps, if you approach it as Zen
Archery.

I wrote:
"All three receivers tuned to different frequencies could simply be
connected to the same antenna. (for frequency diversity)"

I oversimplified the usual case. To avoid interaction between receivers,
a broadband amplifier with one input and multiple isolated outputs is
usually interposed between the antenna and the receivers coupled to it.

I use one of those thick white plastic cutting boards...for kitchen use
normally..cut a part of it into 88" squares.
Then cut a smaller square hole in the wall.
After installing each of the squares on either side of the hole with long
sheetrock screws (my house is old type, with wooden siding in and out) I
then made a few holes slightly larger than the coax on one side and ran a
couple of small holes to feed my twin lead thru.
Nice and weather tight.

I think the trick is to have a separate receiver for each antenna (the receivers having non-coherent local oscillators), and switch between the receiver outputs.

I have just installed a new ball mount and spring in the process of
getting a new HF mobile unit on the air. I put the antenna analyzer on
and with a 20M hastick, I got the SWR down in a good range, but the
impedance was almost 0...nowhere near the 50 ohm target. Do I need
some type of inductor or something added? Nothing in the directions
mentions anything except adjusting the length for best match. What am
I missing if anything?

Try looking at the direction of the currents in the balanced line as
compared with the currents in the flat-top. They are in phase in the
flat-top but opposing in the balanced line.

Now, how can that balanced line possibly be a radiating part of the antenna
when 99.9999% of the power in the line is NOT radiated?

If you can figure out how to get the two line currents in phase, then
please explain it to us. And what effect that would have on the input
impedance of the line . . .

4383. Combining antenna modeling with real-world feedline calculations

Newsgroup: rec.radio.amateur.antenna
Date: 2002-09-03 08:28:51 UTC
From: ac6la@arrl.net
Message-ID: <960228f1.0209030028.638b7cb5@posting.google.com>
Source record: 135274

The latest version of the freeware MultiNEC program can incorporate real-world feedline calculations into your antenna model. You have a choice of approximately 50 different types of coaxial and parallel wire lines and you may add, remove, or change the feedline at any time. The feedline calculations are done external to the normal NEC or EZNEC calculations for the model.

The advantages of doing separate calculations for a feedline, as opposed to using the NEC TL facility, include: no need to add a separate wire to the model to serve as the anchor for the station end of the line; no need to re-calculate the entire model just to change feedline parameters such as characteristic impedance or length; and the ability to include the effects of line loss in the calculations.

Note that this function models only the impedance transformation effects of a non-radiating transmission line attached to the antenna source point. Transmission lines that serve as an integral part of the model, such as those used with phased arrays, must still be modeled with the NEC TL facility.

MultiNEC now also includes a Smith chart sheet. You can see an example at www.qsl.net/ac6la/adhoc/mnsmith1.gif (~30 KB). The antenna in this case is everybody's-favorite-to-talk-about 102 foot doublet of #12 copper at 50 feet above real ground, calculated with a frequency set of 3.5 to 4.0 MHz, 7.0 to 7.3 MHz, and 10.1 to 10.2 MHz in 0.1 MHz steps and with frequency steps between the bands of 0.25 MHz. (Frequencies in a MultiNEC sweep need not be evenly spaced.) The wire was divided into 53 segments, about 50 segments per wavelength at the upper end of the sweep range. In the above Smith chart example the blue trace shows the R and X values at the antenna source and the red trace shows the impedances as transformed with 40 feet of Wireman 554 ladder line. (Parameters for Wireman line courtesy Wes Stewart, N7WS.) The chart is shown with a 50 ohm center and with the green dot marker placed at the 3.5 MHz point. You can change the Smith prime center if desired. The screen shot at www.qsl.net/ac6la/adhoc/mnsmith2.gif shows the same impedance points but on a chart with a 360 ohm center (the Ro value of the feedline) and with the marker on the 10.2 MHz point.

The latest MultiNEC release has several other enhancements, including the ability to show 3D radiation plots using the EZNEC, NecVu (Nittany Scientific), or 4nec2 viewers. For more details and a free download file see www.qsl.net/ac6la/. MultiNEC requires Excel 97 or later.

> partner...

Hi Fred, Thanks for the input. I can't quite see the logic in this
though. I believe current does flow on the braid side of the antenna.
I sure wouldn't want to touch the braid while trasmitting. (While I
was in the Army signal corps, a fellow was sitting in the radio room
and heard a sizzling sound coming from one of the coax lines. Out of
curiosity he touched the connector! He had a really bad finger for
several months afterward.)

If current does flow on the braided side, it would stand to reason
that those sides of all 3 antennae would be hot. If no current flows
on that side, it seems a waste of time and money to have it there at
all. No?

I appreciate your reply, but it still doesn't seem to make a lot of
sense to me, how this works. Respectfully, Justin

Source record: 135279

Roy & Gary:

Diversity reception has been extensively studied for cellular radio
and is widely used there.

Roy is describing "switched baseband diversity," the oldest and
simplest to implement. Monitor output S/N (not necessarily a simple
task to determine on an HF circuit) and switch to the receiver with
best S/N. Simplified version would be to switch on AGC, if you have
two receivers that track, and assume (hope?) that the noise levels are
similar for all diversity channels.

If you want to see an interesting diversity schemes, go a Google
search for "maximal ratio combining," originally developed by
Motorola, I believe. As I recall, you can pick up 3 dB gain in the
best case with maximal ratio combining. This scheme could be used for
HF as well.

At cellular (800 MHz) and PCS (1800 MHz) frequencies, polarization
diversity (V & H feeds ona common antenna) are increasingly popular.
In significant part, this is due to the expense of separate
receive-only antenna and feedline. But, the Rayleigh fading
environment at these frequencies is quite different than the two-ray
fading that often characterizes HF ionospheric propagation.

Sounds like a measurement error. If your SWR is ok, "under 2:1" and
you read the impedance as nearly 0, something seems wrong. "Not with
the antenna". I can see a fairly low impedance as normal, but not
quite that low. MK

If you are interested in a "public debate", lets discuss the merits of a very simple example. Presume that you have a cylindrical volume: 6 cm in height and a radius of 1.5 cm. We want to design a monopole (no capacitive top loading, no short-circuit folds, only a single piece of wire) that is self-resonant at 350 MHz. The wire diameter is 0.5 mm. Use your Genetic Optimizer to design a fractal antenna that exhibits maximum radiation resistance, maximum bandwidth and maximum efficiency. Geometry and total wire length are your variables. The antenna is to be base fed and mounted

over an infinite ground plane. Once you present an optimum fractal design, we will compare it to some classic and arbitrary designs (geometries).

This simple exercise will highlight the fundamental relationships that exist between the physical properties of the antenna and its electrical properties. Additionally, it will illustrate the fundamental trade-offs that exist in trying to simultaneously maximize these three electrical properties of the antenna.

My hypothesis is that the antenna geometry and total wire length together establish the effective height and effective volume of the antenna, which, as a function of resonant wavelength, determine the antenna's radiation resistance and bandwidth properties. Maximum radiation resistance will be exhibited by the design with the smallest physical diameter within the volume, while the maximum bandwidth will be exhibited by the design with the greatest physical diameter within the volume. However, occupying the same physical height and physical volume, and being resonant at the same frequency, all of the designs will essentially exhibit the same radiation resistance and bandwidth. There is no special geometry, fractal or otherwise. There is no fractal geometry that exhibits special or unique characteristics. The only real trade-off will be in the antenna efficiency, where the geometry that is self-resonant with the least total wire length will exhibit the highest efficiency.

Additionally, with a very simple formula, I can predict (approximately) your radiation resistance and bandwidth independent of both geometry and total wire length.

If RF current flows on the outside of coax cable you have developed a real problem in the antenna or
feedline system. Your buddy who heard the sizzle inside a connector was hearing the result of that
problem, and the RF which bit him resulted from that problem, not from normal operation. The fault
caused the RF to go to the outside of the shield where it will not go under normal operating
conditions.

Moral of the story is, when it sounds like something is abnormal, keepa ya fingers off! Or else!

Dick

Could be, but maybe not. Sizzle can result from a problem completely within the connector where no RF appears on the outside of the cable. Nature of the sound may be an indicator.

The connector may not allow RF to escape but is never the less a good heat conductor and burns your buddy`s hand.

Dick Carroll`s advice is good. If it might be hot, don`t touch it.

Best regards, Richard Harrison, KB5WZI

So how do you explain that to yourself? If the impedance "was almost 0"
then the SWR would be sky high. If the SWR is "down in a good range"
then the impedance cannot possibly be "almost 0".

Dick, W6CCD wrote:
"What if the lines are 20-feet apard?"

Assuming 20 feet is significant in terms of wavelength, substantial radiation may result. Over ordinary earth, unless the height were many times 20 feet, substantial loss could be experienced in the earth and not much r-f might get away. Lotsa variables here, line length, etc.

The effective antenna produced by transmission line spacing is the distance between the wires and it has the same polarization as the route between the wires.

George made the same point by benting one transmission wire 90 degrees in one direction and the other by 90 degrees in the opposite direction to form a dipole. One could also widen the transmission line into a Vee or a rhombic. These radiate very well. Current is in-phase in the perpendicular wire componrent while it is out of phase in the parallel wires.

Scott,
Using either an inductive or capacitive impedance matching device is a good idea. At best, the 'R' of the match (R+/-J) is only going to be something around 25-35 ohms without the matching device. With one, you can get the (R+/-J) much closer to 50+/-0J. Just adjusting the length of the HamStick won't do it, with any 1/4 wave vertical.

Justin,

Actually, you came up with a good reason for using a balun. If each antenna had a balun at the feedpoint, there would be no RF on the braid; that is why they are sold. As for the switch, it will work regardless. The side of the connector on the back of the radio that connects to the braid is GROUND. So, the part of the unused antenna that is switched off is just grounded.

You can reduce the amount of RF floating around by connecting the grounding lug on the back of your radio to a cold water pipe or some other ground. Or, perhaps in addition, ground the braid of the coax at the point where it enters the house

Hi Chip

Thanks for the quick reply. To your first point, I have not seen any of your work in print, and it is my belief from reading your own posts that you have had all web-based information on this subject removed - those requests for removal that I have seen have always been accompanied by various threats of legal consequences for non-compliance. This seemingly agressive stance may perhaps have tainted the debate somewhat to the point where all sensible discussion seems to end in a flame war of which I wish to have no part.

To your second point, I will indeed respect your wishes and not ask you or those persons I know to be your affiliates for further details of your technology. It is your right to remain silent if you wish. I trust however that I will not cause offence if I ask from time to time if you have changed your mind yet. Furthermore I trust I am free to continue to investigate and discuss fractal antennas with whomsoever I see fit, so long as they are not your affiliates, nor is it a discussion of a commercial nature.

In your last paragraph you reprimand me for the making of "false attriibutions". Personally I don't email people from NG's since I don't like uninvited emails myself. Record checking, via the web anyway, reveals an endless stream of dead-ends. A bit like stumbling around a dark rabbit warren without a torch. My interest in alternative antenna design theories is a recent one, certainly post 1995. My comments in my previous post were in all sincerity my take of the situation as I see it. I would be grateful if you did not assume that just because I disagree with some aspects of the manner in which you have addressed the debate that it therefore follows that I am attacking you. That is not the case.

Kind regards

Thanks Richard. Indeed my spelling was correct. My trouble in understanding this fractal antenna business is that I fail to understand why fractal form would radiate better than any other wire bending technique.

Interesting looking site by the way. I have bookmarked it for a proper visit later.

Kind regards

In discussing matching possibilities for Floyd's vertical antenna, Wes Stewart wrote...

> A better solution (an exercise left for the reader) is to shorten the vertical
> element to make the feedpoint capacitive and use a shorted stub across the feed.

Another Excel program, MultiNEC, can do the calculations for you. As a matter of fact one of the MultiNEC examples is almost this same situation, except that the antenna is a Yagi and the shorted stub is open wire line, in which case the stub is called a "hairpin" match. However, if you assume that the length of the vertical section of Floyd's antenna can be adjusted to give a capacitive feedpoint reactance while changing the resistive portion of the feedpoint reactance only slightly, and you can mentally switch between thinking of the stub as a section of open wire line to thinking of it as a section of coax (both with a shorted far end), then you can read the MultiNEC example description at www.qsl.net/ac6la/mnex5.html. This example shows how to use the MultiNEC "automatically change the model" function in order to resonate the model.

Now I'll be the first to admit that MultiNEC is not the right tool for everybody. It requires that Excel 97 be available and assumes that you have at least a bit of experience using Excel. It loads and runs slower than a compiled program. And it has a learning curve to be climbed before you can take full advantage of it. As the above example cites, you can also use alternative techniques to determine the parameters of matching sections. The HAMCALC suite from George Murphy has several such programs, and a Google search on "impedance matching stubs" yields 2070 hits (the first of which is probably not what you had in mind). I think one or more of Reg's programs will do the job also. Using MultiNEC per the above example is just another method.

Hi,
Reading a book "Shipboard Antennas", I see many "fan" communications antennas comprising 3 or 4 wires tied together at the top of a mast but fanning out toward the deck with each wire fed some distance (can't be sure from photos but looks like about 5 to 10 feet) from the top.
Anybody familiar with the details and pros/cons of such configurations??
TIA, K3DWW

The problem is that the A99 works, and the performance to cost ration
is really good. Yes, it's cheaply made, and you'll probably have to
replace it in three years after the fiberglass wears out.....but then
you can get the next great coaxial antenna that hits the market. :)

>Optimizer to design a fractal antenna that exhibits maximum radiation
>resistance, maximum bandwidth and maximum efficiency.

This, of course, presumes there is some element of truth to the speculative optimizer package. Again, Genetic Optimization further underlines that total lack of science in this form of hi-grading the population of all antenna forms for suitability - and then comes the back fill of claims of invention and scientific advancement (again, without supporting documentation).

Basically, the fractal community appears to be migrating away from their inability to support their claims or describe their processes; towards an anonymous software packages that admittedly convey no sense of what they are doing much less why. This makes the fractal community's job so much easier when asked "howcum," and they can now respond (with genuine honesty) "dunno." This, of course, can abrade some tender egos and from that quarter you can fully expect a response somewhat more lame such as "fully optimized" (self referential tendencies predominate from the shallow end of the academic pool).

>Geometry and total
>wire length are your variables. The antenna is to be base fed and mounted
>over an infinite ground plane. Once you present an optimum fractal design,
>we will compare it to some classic and arbitrary designs (geometries).

This would be novel indeed, if it actually comes to fruition.

>
>This simple exercise will highlight the fundamental relationships that exist
>between the physical properties of the antenna and its electrical
>properties. Additionally, it will illustrate the fundamental trade-offs

Hi Steve,

You may not be aware of it, but it appears you have already won the
debate. You have been too clear in the format of discussion and there
is scant chance that marketing can respond without swapping the
dictionary of basic electrical design for Roget's Thesaurus.

fractal emergence:
an undocument occassion at roughly 4 AM some years back
when the sudden release of design tension brought forth a new
marketing product;
fractal challenge:
losses to the extent of 6:1 overwhelm fractal champion;
fractal science:
none known to exist;
fractal publication:
failure to respond, fractals cannot compete in the real world,
fractal scientists (sic) have to travel in pairs to accomplish one

presentation of newly discovered marketing terms;
fractal debate:
failure to appear, fractals move into the infomercial 4AM time slot after the porn channels go off the air. Marketing reports new enthusiasm from their core constituency - they weren't all ready to turn off the TV yet (or they were otherwise occupied such that they could not free a hand to turn it off). Marketing offers that they will soon have proof from Arbitron that fractals elevate libido....
fractals challenge viagra:
venture capitalists storm the gates.
fractal bubble bursts (actually sags, tumescent):
venture capitalists demand their money back. Genzu knives replace the 4AM infomercial spot and simultaneously kill the porn channels as the collapse cascades across the board.
fractal rescue:
Bush makes a speech noting the impressive marketing terms that have been brought to us by fractals;
fractal end:
The market plunges 342 more points on Bush's announcement.

Now we have closure.

Vito:

The "Fan" or more commonly, the "Twin Fan" is an HF antenna used on Naval ships to cover the 2 - 4 MHz, 2 - 6 MHz or sometimes the 2 - 8 MHz frequency spectrum. In many cases, they may be used at higher frequencies for receive purposes.

The twin fan antenna is comprised of two sets of 3 or 4 wire ropes which are fabricated from insulated phosphor bronze wire and are suspended from the yard arm of a foremast or mainmast using Delrin insulators. The three or four fan wires will be typically connected to a single point at some deck level using another Delrin insulator. The antenna is top fed with a broadband matching network located on the mast. The matching network is designed such that these antennas exhibit a maximum SWR of about 3:1 over their full operating band.

3 or 4 wire ropes are deployed in a fan configuration as the bandwidth of this structure is enhanced relative to a single wire rope. "Fans" are used in place of a vertical monopole because, as you are aware, low frequency wavelengths would require a vertical structure that would not be deployable onboard ship. The fan lengths may typically be on the order of 60 - 80+ feet in length.

The purpose of the fan is not to act as an antenna in and of itself, but rather, it excites currents on the ship's superstructure which are then re-radiated. The twin fan is typically optimized to excite vertical currents within the mast to which it is connected. At these low frequencies, the ship's superstructure is acting as the "antenna".

The advantage of the fan antenna is its bandwidth characteristics and its low vertical profile relative to a full size 1/4 wave monopole.

Such antennas are directly taken from Oliver Lodge's work: these included the first (1897) patents on antennas, a far as I can tell. Lodge's work was simultaneous with that of Hertz and led to the first practical wireless system. Note that Marconi bought up Lodge's patents.

Lodge realized that particular geometry gave him broad band characteristics, effectively 'bow tie' geometry. Ironically, Lodge wanted syntony--narrow band resonance-- and to do this he placed inductance (coil) between the two 'bow tie' like fans.

In Lodge's own words, this fan/bow tie arrangement was his intepretation of a broad band capacitor or 'Leyden jar'.

Your ship used fans as broad band antennas.

Or,
> perhaps in addition, ground the braid of the coax at the point where it
> enters the house
>

So far this seems like the simplest answer to the question, needing no further explanation. Just accept that the braid of the co-ax is basically ground, and therefore all 3 antenna's (should) have a common ground connection anyway. If you mount more than one antenna on a pole or mast, usually the ground of all the antenna will be common (i.e. the mast), and if you earth the mast to a earth stake, then you are again creating a common earth for all antenna, radio, etc.

In fact, I have had installations where I didn't need to connect the radio to the power supply negative as the ground connection was made through the antenna. So, what's the use of disconnecting the braid at the antenna switch if they are all connected together anyway via the earth???

Hi I am about to put a G5RV up in my garden and because of length restrictions it will have to be mounted in an inverted V configuration. Also one end of the wire will have to run along side and close to the end of the house. The drive wire will be out in the open.
Will having part of the aerial close to the side of the house degrade the signal, etc.

This is a CORRECTION.
I wrote"---it was Ampere who said: "The induced voltage is proportional to minus d phi / dt."
Bart Rowlett e-mailed me: "Nope, it was Faraday."

I looked it up as I should have before posting something that proves wrong. Bart is exactly right.

I am sorry for misleading with a wrong statement and will try to check my facts if in doubt, or remain silent.

Best regards, Richard Harrison, KB5WZI

The issued patents are (of course !) available on-line at www.uspto.gov.
They're fairly easy to find using the search function and a few well-chosen
keywords or perhaps a name. You may need a TIFF file reader (such as
Apple's QuickTime, or InterneTiff) if you wish to see the images.

It's all pretty easy, but post again if you have any problems.

What is a 'drive wire' on a g5rv ?

Anytime the antenna is not out in the open there is some degrading of the signal.. It might be measured in tenths of a db or less . If it is mounted mext to a metal guttering it could be a lot.

Numerous papers have been published touting the advantages of fractal antennas, and a number of them have claimed that the fractal form is innately superior in one way or another to all possible alternate forms. However, to my knowledge, no real evidence has been provided in any of these papers to substantiate the claimed superiority. Steve Best, VE9SRB, has presented at professional forums a number of non-fractal designs which are equal or superior to similar fractal antennas by a number of criteria. Some of these can be found as EZNEC files (with accompanying explanatory text files) at my web site, at ftp://eznec.com/pub/MI2/. They were also at the ARRL web site, unless the ARRL has been intimidated into removing them.

If anyone does know of a published paper that presents testable evidence that fractal antennas are superior in any way to all other folding methods, I'd appreciate a reference.

Hi Alec,

Please feel free to correspond (or better yet) offer questions on this
board or make observations that relate to this subject (which is, of
course, the raison d'etre of this assembly).

As my site extends to some 300+ files of data, models, and reporting;
it can be overwhelming to the casual visitor. In fact, I will be the
first to admit it takes considerable patience to even begin a review
of the data.

The practical approach is to abandon any notion that these structures
are suitable for erection. You should note that I employ "perfect"
scenarios and only monopoles by and large. The reasons for these

choices are they level the playing field for cross-correlation between all the different models; and by being monopoles I can double the number of points available to me through the 'mirroring' of ground.

I approached this family of design through two key variables:
height,
amount of wire consumed
I typically constrain the height to 16 meters tall
OR
I constrain the wire consumed to 64 meters of wire.

Either results in a structure that would find some HF application, with modest height. I thereby have two interleaved studies being conducted when I take a family of fractal curves and drive them over a frequency span of 5 to 30 MHz. This range of frequencies constitutes a third constraint.

For each fractal form, I further elaborate by extending the survey to include up to 6 iterations for that form. So these studies then go to look at the response across all similarly constrained iterations for the several fractal forms (about half a dozen or so). This constitutes a third parallel study into the affect of iteration, specifically and generally (compared with its cohorts). This work also offers a fourth constraint to the general fractal.

So there should be a pay-off. When asked a general question, this work should support a general answer (much like the equation for a dipole's length). That element is there too, but very provisional. Just within these four constraints I describe, you find that same 300 pages of data - I can offer a general statement: it's in the kinks - there is no shape attribute. This was confirmed some years later by Steve Best's V9SRB designs shown to this group in Oct/Nov 2000.

Thanks for the info, I will probably just run some wire for now till I can buy a good antenna.

You are correct, 108 to 117.95 are NAV frequencies, but these freqs are often used by Flight Service Stations to reply to pilots requesting information on a different frequency.

DC is definitely better than AC because of less sparking at brushes. Longer brush and commutator life is the result. The motors were designed for 24-28 volts DC.

There were excellent articles in QST about 1971 describing maintenace, lubrication, and control circuits.

Source record: 135319

Hi Steve,

Great to hear from you; trust things are going well. Hope to see you in Baltimore, if I can break away..

You publicly posed an interesting benchmark for the Fractal Genetic Optimizer which I think sounds like a great idea to try to beat. I have some initial thoughts for you as we move towards proceeding:

1) Please write up the figure of merit (cost function) you wish to pursue. In this way, there can be no disagreements that the FOM was chosen a posteriori, and thus bias any result in some way. Merely saying 'best bandwidth; best radiation resistance'; and so on begs the issue. It needs to be defined mathematically in a way that includes all the criteria and weights them in a reasonable way. I will step out of the process entirely so as to not even project a hint of bias. A good source on cost functions is: "Practical Genetic Algorithms" by our colleagues Haupt and Haupt, (Wiley, 1997). Our colleague Ed Altshuler is also well known in this context (he and Derek Linden have a patent for 3D optimized antennas from conventional GA's) and may be helpful in fine-tuning.I also understand that you are in conference with other well known antenna folks, who should have a good bit of knowledge on this.I strongly encourage this.Let's all have some fun!

2) The most scientifically compelling way of demonstrating whether an antenna design is 'better' than the one you want to benchmark is to include it directly into the first generation of the genetic optimization. The best always stays at the top, so to speak, so if your design is the best it will remain so through several generations, and remain the best to the last generation. If not, well, we can stop in just a couple of hours of sims!

3) The modeling of such an antenna on infinite ground is problematic. First, by forcing mirror symmetry, you constrain other non-mirror symmetries in the design space. Why throw options away? Second, there are NEC problems modeling wires very close, and with a parallel projection to, ground. Third, we need to think about a practically realizable antenna, that others won't bicker about being a remnant of the sim. My suggestion is that we dispose of the infinite ground and force any ground plane/counterpoise to fit within the form factor you specified.Alternatively, turn your monopole into a dipole. Fourth, are we talking about an antenna or an antenna system? Are you allowing for funky 'v' shaped excursions that short to ground? Fifth, let's agree that for an antenna with a single current max, the radiation resistance is the resistance at the maximum current position.

I hope we can all make some progress on this; I seem to recall extending you such an invitation 3 months ago to present such an interesting design problem. But we are all busy, so the delay is understandable. Here, we just finished a

science project on the FRAGO, and it will stay on a series of commercial projects until about 15 Oct. Then a short break; a good time to pursue. That interregnum from now should give you plenty of time to iron out the above, for which I am happy to continue discussions.

I think we will both find this exercise enjoyable, as well as benificial for the edification of our antenna comrades.

I am posting this so others may follow our progress.

With Warm Regards,

Chip N1IR

Larry,

The most successful portable type antenna I have used so far is a shortened 20 meter dipole made from 2 hamstick type antennas. I picked up 2 of these new at a local hamfest for a total of $26.

Assembly is very fast (~ 10 minutes)and I'm using an extendable "paint pole" as the support. Total length of the dipole when assembled is around 14 ft and it is very light in weight.

With this antenna at only 12-15 ft. I've been able to work a lot of stateside and a good bit of cw DX (Europe, Africa, South America).

I have also been using a "12avq" (as a ground plane) -- not as a portable -- and even at a modest 10 ft. or less off the ground I have had very good success on 20, 15 and 10 meters.

On both of these I have been using a MFJ-971 tuner

Lars,

I was thinking about doing the same thing with two Hustler MO4 - 22" masks and Rm-20 resonators. It would be a little shorter thant the ham sticks (and perhaps not as effective). Question - how do you connect the two antennas together to for the dipole?

Pict,
basically, the same way. I use a wooden board made to fit
in a window. Drilled a couple of holes to pass the two
conductors of the ladder-line through, shut window on board
to hold it. The board makes an impedance 'lump' in the feed
line, but it doesn't amount to anything significant.
The board also makes for a good place to mount 'bulkhead'
connectors for coax...

The wire can ONLY flow on the outside if it has a return path on the inside.
In most antenna switches the center conductor of the unused antenna is
connected to ground as well.

4440. Isotron antennal. Info wanted.

Newsgroup: rec.radio.amateur.antenna
Date: 2002-09-04 07:23:23 UTC
From: Nisse <Nisse@hotmail.com>
Message-ID: <3D75B4EB.2D2D565C@hotmail.com>
Source record: 135331

Hi group.

I've been looking on the net, searching for a limited-space antenna for 80mtrs. As these small antennas always has low efficiency, I would like to use 100W output. If I modify my magloop for higher power, I'd need a capacitor good for some 8kV. These thiongs are hard to find, and very expensive. The home-brew-capacitors are all to small (in capacitace).

So, I by accident triped on the "Isotron". It is claimed to be quite broadband, but yet very small. This in my eyes means not low, but VERY,VERY poor efficiency.

1) What is this thingamajig anyhow? Is it some magic "EH"-stuff, or is it a real antenna?

2) What is claimed in terms of dB relative dipole for the isotron (magloop claim for 80: -6dB in GOOD cases, approx -10dB according to my own experience)

3) Is it possible to build one at home, and where can I find the neccesary data to build one for myself?

73 de N.

<snip>
It won't make a lot of difference if you're using
coax or ladder line to feed the antenna. You can only
'stretch' an antenna so far.
'Doc
<snip>

Unless you mean mechanical stretching ;-) I see no reason other than line losses and losses in the matching circuit why the antenna length has anything to do with it being an effective radiator or not.

4442. Tunable Balun Idea

Newsgroup: rec.radio.amateur.antenna
Date: 2002-09-04 10:40:36 UTC
From: marvin rosen <raghead@worldnet.att.net>
Message-ID: <Eqld9.9726$jG2.734324@bgtnsc05-news.ops.worldnet.att.net>
Source record: 135333

A 1:1 balun can be made by winding 6-10 turns of
coax around a 5" diameter form. Would it be feasable
to insert a 7.5" X .5" ferrite rod in the middle of this
form to vary the inductance by sliding it back & forth?
The above would only be used with 100 watts output.

Source record: 135334

Hi !

We did a small fieldday operation 08/17 - 08/18, one of tbe participants brougt a Ft-817 with external power supply to achieve 5 Watts output.
He brought 2 portable antennas as well, the "Miracle Whip" and annother one, shaped like the outbacker, using plugs to change bands, on top a telescope whip.
Receiption was fine with both antennas but he could not make any contacts on HF, so he wondered about the ability to send with the radio. However a quick test on our "FD4" showed the radio being fine.
Since i brought my "MP 1" to the fieldday as well, i set it up on the beerhouse table we used for breakfest and hoooked up the "FT-817", we got several contacts on 10m two of them with "59" reports from bulgaria , the other two antennas mentioned above gave no contact at all, our QTH in North Germany (nr.Hamburg).
The "MP 1" fits dissambled in almost any briefcase, it takes up to 150 Watts. It does not need a tuner, since you tune it to the frequency by using a "sliding cap" on the loading coil. Disadvantage ist the rather high price for the antenna.
You can find more information abou the "MP 1" on http://www.superantennas.com (manufacturer) and http://www.eham.net in the "reviews" section.

Arend Harteveld wrote:
"Sea water is a short circuit to horizontally polarized waves---So, it should act as an excellent reflector favoring low angle radiation..."

It does for vertically polarized waves, but the reflection is a killer for low-angle horizontally polarized waves. They experience a phase reversal of 180 degrees upon reflection. The distances traveled by the direct ray and the reflected ray are alnost identical and as they arrive at about the same magnitude and out of phase at the reception point when launched at a low angle, their cancellation is almost complete.

Best regards, Richard Harrison, KB5WZI

Arend Harteveld, PA1ARE wrote:
"So it (sea water) should act as an excellent reflector favouring low angle radiation."

It does only for the vertically polarized signal.

Arend probably doesn`t have the 19th edition of the ARRL Antenna Book readily available there in the Netherlands, but on page 2-17 is Fig 21 showing how the reflection phase reversal makes a 1/4-wave grounded vertical appear as a 1/2-wave vertical. That`s good for low angle radiation.

The story for horizontally polarized waves is presented on page 3-6 in Fig 5 (B). The ARRL Antenna Book says:
"Indeed, at a low enough elevation angle, the phase of the reflected wave will actually change by 180 degrees and its magnitude will then subtract from that of the direct wave. At a zero takeoff angle, it will almost equal in amplitude, but be 180 degrees ouut of phase with the direct wave. Complete cancellation will result in a null inhibiting any radiation or reception at zero degrees."

That means no ground wave and almost no low-angle radiation from a horizontal antenna at low altitudes over highly conductive ground or sea water. Marconi put radios on ships. The Marconi antenna is vertically polarized. The horizoontal wire between masts doesn`t effectively radiate, it only provides capacitive loading for the vertical feedwire which is the only effective radiator.

Best regards, Richard Harrison, KB5WZI

Steve said:

"If you are interested in a "public debate", lets discuss the merits of a very simple example. Presume that you have a cylindrical volume: 6 cm in height and a radius of 1.5 cm. We want to design a monopole (no capacitive top loading, no short-circuit folds, only a single piece of wire) that is self-resonant at 350 MHz. The wire diameter is 0.5 mm. Use your Genetic Optimizer to design a fractal antenna that exhibits maximum radiation resistance, maximum bandwidth and maximum efficiency. Geometry and total wire length are your variables. The antenna is to be base fed and mounted over an infinite ground plane. Once you present an optimum fractal design, we will compare it to some classic and arbitrary designs (geometries).

"This simple exercise will highlight the fundamental relationships that exist between the physical properties of the antenna and its electrical properties. Additionally, it will illustrate the fundamental trade-offs that exist in trying to simultaneously maximize these three electrical properties of the antenna.

"My hypothesis is that the antenna geometry and total wire length together establish the effective height and effective volume of the antenna, which, as a function of resonant wavelength, determine the antenna's radiation resistance and bandwidth properties. Maximum radiation resistance will be exhibited by the design with the smallest physical diameter within the volume, while the maximum bandwidth will be exhibited by the design with the greatest physical diameter within the volume. However, occupying the same physical height and physical volume, and being resonant at the same frequency, all of the designs will essentially exhibit the same radiation resistance and bandwidth. There is no special geometry, fractal or otherwise. There is no fractal geometry that exhibits special or unique characteristics. The only real trade-off will be in the antenna efficiency, where the geometry that is self-resonant with the least total wire length will exhibit the highest efficiency.

"Additionally, with a very simple formula, I can predict (approximately) your radiation resistance and bandwidth independent of both geometry and total wire length."

Fred, Marty, Dick, all... Okay I believe I understand. Many thanks to you all. I'm in electronics technology at the local tech school and even my instructor was unsure on this as his field is not in antenna / RF situations. I figured if I posted my question here, there would be enough knowledge and experience represented that I'd get answers. It is good to have rec radio as a resource for those things that nobody can answer on a local level. Many thanks, guys! I appreciate you. Respectfully, Justin

Yep. You are missing Heinrich Hertz, who invented this antenna
about 50 or 60 years before Louis Varney. The antenna is a centre fed
doublet or dipole. G5RV is correctly applied only to the coax/twin
line combination antenna, although Mr. Varney was very confused
about the exact length of twin line required, and published
various values in different articles. He was, however, quite
clear that an ATU was required. If I was to publish the design
again, could I call it an 'M3ABC' antenna? No, I thought not.
The truth is that Varney didn't invent anything, he was just
President of the RSGB and they humoured the guy. He really
didn't seem to understand that any length of transmission line
will act as an impedance transformer, be it coaxial or twin.
He seemed to believe that coax didn't do any transformation

and could be operated at high SWR without losses.

Then you would have a radiating section at the base of the line where you achieved the separation (unless you have a _very_ big PA ;-) and some detectable imbalance in the near field, but at any significant distance from the line (more than about 4 times the separation) there would be a very small signal. I recommend you read Feynman's 'QED', remembering that radio and light are the same things at differing frequencies.

Feed it with ladder line. Use a Transmatch/ATU. The losses in coax,
even LDF4/50, would be horrendous, unless you want that QRP effect.
Try to get the poles further apart than the length of the doublet
and use an insulating line to connect to it's ends so that the ends
are as far away from the poles as from the ground. Any length of
doublet will work but longer is better. As you have 200' to play
with you could try 135'. see W4RNL's page
http://www.cebik.com/gup/groundup.html
chapters 5,6,11 and 12. The Whole site is great!!!

> resonance.

Indeed, and the point of lowest SWR might well not be the point of
resonance either. I.e SWR is one at 50 ohms impedance, reactive or not.
SWR is a _very_ bad measure of resonance.

Two little known facts about the G5RV

1. It won't work on all bands without an ATU (a real one, not the built in sort).
To quote G5RV himself:
"the use of a suitable antenna tuner is necessary on all the other hf bands
because, on those bands, the antenna plus the matching-section will present
a reactive load to the feeder"
see http://www.qsl.net/aa3px/g5rv.htm

Here are some impedances at the end of the G5RV twin line

MHz Twinlead/Coax Junction Impedance 50 ohm Coax SWR
3.8 14.6 + j2.9 3.44
7.2 27.9 - j54.8 4.3
10.125 31.6 + j274 50
14.2 103 - j49 2.6

18.14 44.3 - j290 40
21.3 24.2 + j80.7 7.8
24.95 79.3 + j41.5 2.2
28.4 3049 + j655 64

see http://www.qsl.net/k2hq/g5rv.htm for more detail

As you can see, the antenna is not resonant on any band. No
figures given for topband although most ATUs will tune it up
without strapping the feed together. Varney chose a good length
for the feedline which got reasonably low reactances on all the
non-WARC bands, but the ATU should be at the junction of the ladder
line and the coax. SGC make just the thing....

For more impedance figures for the 'raw' antenna - 102' dipole see

http://www.cebik.com/gup/gup6.html

2. It is _much_ better if you throw away the coax. It is also then not a G5RV.

Operating coax at SWRs like those shown is a sure way to
dissipate power without radiating it.

Having come across this discussion relatively recently, but knowing the heat that it generates, I would say that Chip is just trying to establish some ground rules that can be used for quantitative evaluations. The better defined the decision rules are, then the better the chance of a definitive outcome.

Andy,

Chicken wire is a very bad idea. It is galvanised. All the RF flows in the zinc coating and this has a high resistivity. Stick to copper, unless you own a silver mine. Aluminium is a possibility, I suppose, but has no advantages and is a b*gger to solder. Keep all the connections as low resistance as possible. Remember that RF runs in the surface not the bulk material.

4460. Re: Isotron antennal. Info wanted.

Newsgroup: rec.radio.amateur.antenna
Date: 2002-09-04 16:20:46 UTC
From: 'Doc <w5lz@icok.net>
Message-ID: <3D7632C2.9326B580@icok.net>
Source record: 135352

Nisse,
The 'Isotron' antenna is basically a tuned circuit
consisting of a coil and a capacitor. The coil is
wound on a form, the capacitor is made up of two or
more plates/surfaces. They are not too 'broadbanded',
as with any tuned circuit, the higher the 'Q', the
narrower the usable bandwidth (as an antenna).
I have no idea of the gain of an 'Isotron', but it's
going to be a -dbd, not as good as an ordinary dipole.
That's true for any 'compromise' antenna, though. Depending
on how 'bad' you need a limited-space or 'stealthy' antenna,
it may be what you're looking for. I've used a 10 meter
'Isotron' and it came out the looser with a 1/4 wave ground
mounted vertical.
'Homebrewing' an 'Isotron' like antenna shouldn't be too
difficult. It also isn't going to be too easy. I wouldn't
like to use an 'Isotron' as my primary antenna, but for
limited spaces, or hiding/disguising an antenna, it's better
than nothing...

While I go out of my way to upset the Chipster, in this case he is going in the right direction.

For once the rules will be fixed and understood by all before the race begins. Unlike the "Great Fractal $1000 Challenge" that moved the finish line on a daily basis, and finally declared that participating in the race made a contestant ineligible to win. The prize was awarded (choke, choke, cough, cough) to one of his local lackeys.

I'll think about this a bit and come up with some FOM calculation. I really
don't have a problem with this as a comparative tool.

In my opinion, we could simply determine the FOM for a straight Euclidean
monopole
[or dipole], self-resonant at our test frequency and use this as a
reference. The "optimized" antenna with the closest FOM to this reference
will be judged 'better'.

How you start the optimization process in the beginning is entirely up to
you.

First, I don't have any issue with using a dipole rather than a monopole. I will however, force symmetry about the feed point in terms of both mirror geometry and wire length. This, in my opinion, is a simple and reasonable constraint that should have no relevance in terms of any NEC limitations or the objectives of this study. I have compared NEC results and measurements with tightly coupled (closely spaced) wires and have found extremely good agreement. I do not see this as a limitation. If we have concerns relative to the computational accuracy of any NEC calculation, we can address it as necessary.

Second, for purposes of this study, radiation resistance will be defined as the lossless feed point resistance. This is consistent with widely accepted definitions and should be of no concern since I am forcing symmetry about a centrally located feed point. It's also a convenient point of measurement.

Ken, there are many facets to this subject that are not readily explainable, what with most hams' lack of sophisticated testing capabilities. I've seen lots of antennas that work in ways that theory suggests they wouldn't. My Novice 40 meter dipole wasn't as high as 10 feet off the ground at any point yet I regularly worked over a thousand miles with it using 25 watts.
I've found the best overall antenna for both short and longer range use (not contesting) to be an 'informal' inverted V with the center as high as you are able to get it, and the drooping ends at whatever angle hung wherever one can find to hang 'em. It will work 'em both far and near. Makes it much easier to arrange than trying to get both ends as high as the middle, too.

Modeling a full dipole shouldn't be necessary -- a monopole should suffice. NEC or EZNEC results for a monopole over a perfect ground should be very nearly exactly the same as results for an equivalent dipole in free space (with 3 dB field strength and 2X impedance differences, of course). If anyone is aware of any example where this isn't true, I'd appreciate your sending me an NEC or EZNEC file that illustrates it.

Andy, M3ABC wrote:
"Stick to copper ubless you own a silver mine."

Andy is right. Chicken wire is "galvanised" and is thus quickly deprived of its zinc coating through galvanic action when paired with copper. Aluminum erosion is even faster.

Sheet copper is used by broadcast stations at the tower base to braze all the radials together.
Beyond this joint, no other cross connections between radials are allowed. Ed Laport advises that addituonal connections only serve to encourage hysteresis currents which increase ground loss. It`s the radial current which lowers ground loss. Longitudinal current is to be enabled, not the transverse current. No chicken wire!

Best regards, Richard Harrison, KB5WZI

Hi Roy,

Modeling a full dipole is not necessary. I presumed that Chip's GO was somehow configured for dipoles rather than monopoles. I could go either way.

Dick, W0EX wrote:
"I`ve found the best overall antenna for both short and longer range use (not contesting) to be an "informal" inverted V with the center as high as you are able to get it---."

That`s essentially what Ken put up but his inverted-V is adjacent to his house and little if any higher. Ken`s antenna works over a short sky wave distance but no longer distances.

W0EX`s antenna is likely not coupled so closely with house wiring and piping. If you rob an inverted-V of its vertically polarized radiation you are left with only horizontally polarized radiation from an antenna of very low effective height.

Best regards, Richard Harrison, KB5WZI

4475. Mobile Mount Help

Newsgroup: rec.radio.amateur.antenna
Date: 2002-09-04 22:02:59 UTC
From: ntl user <ntl.user@ntlworld.com>
Message-ID: <3D768313.6010501@ntlworld.com>
Source record: 135227

Thanks in advance.

The bodywork of my car is plastic with no suitable mounting points for a mobile VHF antenna. I have tried a glass mount antenna but it is as much use as an ashtray on a motorbike.

I was thinking of mounting a gutter/mirror type mount to the roof bars, which appear to be made of GRP, and run a separate wire to the chassis of the car. Either one of the seat belt mounting points or the tailgate mounting bolts. I intend to use pvc coated wire rated about 10 Amps.

Would this idea work better than the glass mount antenna.
My intention is to use a 5/8 whip on 2mtrs with a max power of 25 watts.

Or would it be better to try and attach say 3 or 4 quarter wave radials to the gutter mount.
Only problem is that the radials on this gutter mount could not be fitted symmetrically, would this make much difference.
Or would I be better making a custom mount in this case.

Cheers
Hank

Hi Richard,

Apparently NIST does not share Laport's trepidation with radial vs.
grid as evidenced by their Standard ground for testing:

For many years I used an 80 meter dipole that was up only 20 feet at
each end and drooped to
about 15 feet at the center. It was next to the house. I would
regularly work stations several
hundred miles away and hold my own with most stations on the band in
that radius. No trouble
working stations out to around 1000 miles either on a regular basis.
This was when I didn't
know it wouldn't work. (:>)

> As you can see, the antenna is not resonant on any band.

Actually, it's pretty clear that the antenna is resonant somewhere
on 75/80m. All you have to do is move the frequency enough to get
rid of +2.9 ohms of reactance. There may also exist a 40m and 20m
ham frequency where the reactances are zero. All you can say is
that said antenna is not resonant on any of the above listed
frequencies. But the G5RV is resonant on or close to 75m, 40m,
20m, & 12m. Heck, it was designed to be resonant on 20m.

Yep, under stress, it appeared as open wire with about 4 inch spacing.
Z0 was 550-600 ohms with no wind. It was insulated wire and vibrated in
the wind so the dynamic Z0 was a little unpredictable. :-)

Hi Steve,

This is a stale dodge for soliciting free engineering in the guise of
contest. Each of the first 20 winners gets a free T-Shirt paid out of
$10,000 profits. [Who owns the optimized design?] Marketing writes
off the prizes too.

If you want to judge process, then take the same candidate as GO
instead of offering it. That is, you compete as an optimizer (John
Henry style); judged on the basis of two revealed products of
indisputable authoring; constrained to your earlier specification.
This worked to peer satisfaction the last time.

a more general observation:

Speaking of last time, in observance of the bi-annual event we have
suitable examples already in the archive here. Try the defeated
fractal champion of 2000. Design established, FOM established. That
dog, as good as any, certainly should buff up with "optimization" and
compare better to Steve's challengers. N'est pas?

1. Don't go there because it could be optimized;
2. Don't go there because it could not be optimized.

Chance placements can help instead of hurt antennas. The best way to find which it is requires trying it out. Ken has tried and seems not to be so lucky as you.

Dear Group,
About a week and a half(?) ago, I posted a question. I had a horizontal loop on the roof of my apartment building that was sized for 40M. I asked for opinions if I were to increased the size to maximum space available with no thought of the resonant frequency. The replies I got ran the line of "give it a shot; it should still work plus give coverage to 80M possibly even 160M."

Thought I'd give the group the results of the change. I grabbed my trusty spool of 26AWG enameled wire (I've got plenty -- anyone need some? :-), and restrung the loop for max size. Over the Labor Day weekend, my log looked like this:

New Jersey, North Carolina, New Mexico, Germany, Siberia, Denmark, Lithuania, England, the island of Malta, Israel, Czech Republic along with a few others. My QTH is Minneapolis, in the heart of the city.

Thanks for the input, Group. I think it's a "keeper"

> 'Doc

Hi,

Full agree.
As SWL I'm using a mixed simple electricwire soldered to a coax RG58.
The longwire is 40m long and is tied at about 3m high .
My location is on top of "hills", 250m /sea, openfield. In 48hrs I
listened over 87 DXCC and twice as more after 3 months.

But on another location, I use a sloper of 15m connected to an indoor
cable 10m long (so for a total of about 25m of mixed simple electric
wire+coax) but here the signal quality if poor and I have QRM to
generators nearby.
But in both QTH i get a SWR of 1:1 or near or sometimes 1.5 on the 17m
band.

So depending your location the long wire mades of simple lectric wire
or even a coax give excellent results.

I have think to terminate the wire with a terminator but I din't
install it.

See my QTH installation at
http://www.astrosurf.com/lombry/qsl-longwire.htm

NB. To resolve my QRM problem on all HF bands I'm currently replacing
my sloper with a magnetic loop ALA-330.

Hi,

All depends your location and working conditions.
See some comments on http://www.astrosurf.com/lombry/qsl-longwire.htm

In one QTH, on top of hills, open field at 360 deg, I'm using with
great success a long wire of 40m tied at about 3m high. I got my 171
DXCC after 3 months of listening.

On the other QTH I use a sloper 15m located outside + 10m indoor coax
(so 25m) and this "antenna" gives me very poor result due to a heavy

QRM.
So for this specific QTH I'm currently installing a magnetic loop ALA-330. I hope it will suppress my QRM problem created by electric devices.

In your case that depends of numbers of factors, including the ground quality. A dipole can be difficult to install (maybe in inverted V), a vertical is fine but much more visible (otherwise hidden in a flag) and request a mast well attached, and according users portables antenna give excellent results too. So what to choose ?

Be a ham radio means also experiment and test new technologies and devices. So try by yourself and learn in experimenting. Installing and testing antenna is also part of the fun.

I opened up the two messages, one labeled RE:THIS is a VIRUS and the other of THIS is a VIRUS HOAX.

ONE of them caused a message to keep repeating on my screen that Windows Explorer has been infected by a virus. and a bunch of other stuff regarding Alt. something or other.

So ONE OF THEM has to be a VIRUS.....

I clicked on the OK box, to no avail. I had to hit the Control Alt.Delete command to "end" that task of reading the news group, to get rid of it. My Norton is running as I speak, so far it hasn't said anything to me as yet. IS this something that Norton will cure? My version is about 2000 or 2001. I have 2002 somewhere I can install.

Larry,

Sounds interesting

Lakeview Co. makes a device with the connectors on it already, cat. # 901, rotatable dipole mount for about $15 or you can buy the connectors from them for about $8 (#275 and #082) and a piece of flat metal.

There probably are some other suppliers that also supply the mounts ready to go and/or the individual connectors.

This weekend I am going to try to figure a way to mount this as a 1/2 wave vertical and see what kind of performance I can get.

4498. Rule to respect in installing a LOOP ?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-09-05 02:25:38 UTC
From: lombryt@hotmail.com
Message-ID: <db35a0c.0209041825.6f93bb5b@posting.google.com>
Source record: 135238

Hi,

I'm currently installing a magnetic loop ALA-330 from Wellbrook (http://www.wellbrook.uk.com/ALA330.html) as I experiment an heavy QRM due to nearby generators (airco maybe). I hope it will help me suppressing all this(electrical) QRM.

Due to a problem of space available and risk of theft I will first try to install the loop indoor near a window. If the reception if poor I will install it outdoor just in front of the same window but I'm not sure to be able to install in the garden as it is not secure enough to let it alone without attention.

Question:
Do you know if there are rules to respect to install this kind of antenna indoor or oudoor (other than perturbations on human by the magnetic field as I will only use it for SWL activities).
I especially think to the distance to the window or from the concrete wall or from internal house walls or any metallic or magnetic object ?

If I have to attach the loop somehere to a hoock, what material can I use to not influence the reception ? I beleive that any metallic material is prohibited. Have I to use only plastic arms, mast, hoock, and non electrical wires to prevent any perturbation ?

Thanks

Thierry

Neither is a virus. Just a JavaScript loop that can be annoying and you
may have to bail and reboot. No harm done, no infection. Norton 2002
would have picked it up and called it a virus but still thats not what
it is.

I don't use a tuner. 86 ft of 450 ohm ladder-line resonates
my 130 ft dipole on 4 Mhz and 122 ft resonates it on 3.5 Mhz.
Over any single band, varying the length of the ladder-line
is just as effective as varying the length of the dipole.

4505. Need Advice on Remote Antenna Tuner Location

Newsgroup: rec.radio.amateur.antenna
Date: 2002-09-05 03:40:00 UTC
From: Steve KC8PBO <skaatznospam@ameritech.net>
Message-ID: <kmAd9.6799$yt3.3240058@newssrv26.news.prodigy.com>
Source record: 135260

Greetings,
I have a multi-band dipole fed with coax, the total coax run is approx 35'.
I would like to install a remote antenna auto tuner at the feedpoint, but
the mast won't support the tuner at that height. So my question is, if I
mount the auto tuner at a lower point, say 10' down from the feedpoint, do I
lose the advantage of using a remote tuner to tune at the antenna rather
than the feedline?

Thanks

Steve

Roy Lewallen wrote:
"What theory leads you to believe you shouldn`t be able to regularly make 1000 mile contacts with 25 watts using this antenna?"

The dipole wasn`t as much as 10 feet off the ground anywhere and the frequency band was 40m.

Maybe the antenna at the other end of the circuit might be similar. If so, each antenna could be expected to be at a 16 db disadvantage estimating from Fig 12 (A) on page 3-11 of the 19th edition of the ARRL Antenna Book. Two such antennas is a loss of 32 db. The path loss is well over 100 db in addition to the antenna loss. With luck the received signal is around a microvolt.

You likely have noise to compete with. You can make contacts, but regularly?

Best regards, Richard Harrison, KB5WZI

> know it wouldn't work. (:>)

My noted Novice dipole way back when was attached to the house, and the other end to an outbuilding. I've often used antennas attached to the house over the years with no obvious detrimental effect outside some unwelcome RFI. And for years I used a autotuned 60ft wire when camping with the feed end attached to the roof rack which was no more than 9 feet off the ground, and the other end to 10 ft of aluminum tent pole lashed to whatever bush was available, sagging in the middle. Never ran over 100 watts, usually more like 50, and worked about everyone I called, including DX.
Roy is right, of course. If one has no experience you can get fed the wrong idea about what works, and how well, really fast. Optimization is an entirely different matter, of course.

And here's something that needs to be made known for some newcomers, for emergency use. If you find yourself without proper coax connectors where they need to be, and need to make splices in coax cable, just do it. Strip the conductors and twist them together, making sure the two conductors are not able to short circuit together anywhere, and make as many splices as you need to get the feedline wherever you need it. As long as it doesn't short nor get wet, you'll never be able to tell the difference in operation. I like to tape them just for good measure, though.
Of course this sort of thing should never be considered a substitute for properly installing of connectors and cable, but don't let anyone tell you it won't work. It will, at any amateur frequency through UHF. I even used a short length of speaker twin zipcord spliced in to feed a Direct TV sattelite antenna signal through a small hole in an aluminum window frame where there wasn't room for the RG6 cable in a temporary situation. Worked like it wasn't there.(If you try this make sure you preserve polarity since the DC for the feedhorn electronics feeds up the cable as well as signal feeds down it. Cross em and you fry the feedhorn LNB)

I get the feeling that some hams would be off the air if things weren't just "so", even in an emergency. Like if you can't buy it at HRO it won't work.

What you need to use is a 26" long whip in a magmount on the 4 foot square roof of a car. This is a quater wave antenna and will have the best reception pattern (to the horizon and to the sky, and will also allow transmit with a decent match (SWR).

The center of the coax from the radio just goes direct to the whip with no coils or any complications. The magmount will provide a decent ground at VHF.

The CB magmount is likely to have a shunt fed loading coil in the base. This will degrade the received signal for VHF since its intended for HF at 27 mhz not 110 mhz.

All

I go camping quite often and bring along the HW8 or TenTec Scout.. Ive used a full sized G5RV with good success. However, not every place I go has trees or a structure that I can attach an antenna to.

I do like working 80meters in the evening and 40 20 and 15 meters also. With the G5RV along with the need for place to hang the antenna I've also noticed stray RF floating around and if a mic is used with the scout RF can be found there not good.

So what is a recommendation for a good portable antenna that can be used for camping or emergency work.. I have a Gap Titan DX but its not exactly small or portable although I have moved it several times for Jamboree on the Air for the Boy Scouts.

Any recommendations of a good portable antenna?

Thanks

Ah, yes, that's a different story. But which gospel? Pretty much all the physics texts have the same theory. In contrast, the Portland phone book Yellow Pages lists 107 categories of church, each with its own guaranteed for-sure true gospel. And Oregon has the fewest churches per capita of any state.

Unfortunately, too few people can distinguish between theory and gospel.

Rich

IMHO you should stick with the G5RV (or any doublet). It is pretty good for a multiband portable - and will fit in a carrier bag!

Why not invest in a portable mast to hang the doublet centre from if there are no trees. Can arrange it as an inverted V with just a couple of big tent pegs and some fishing line - incidentally see http://www.tackleworld.co.uk/acatalog/index.html?http%3A//www.tackleworld.co.uk/acatalog/Tackleworld_co_uk_Trolling_Handlines___Mackerel_Feathers_Spinners_61.html&CatalogBody for good supplier of Cardolene - either size OK - this is great stuff for 'stealth' aerial suspension.

I got a 10m mast for about £50 from the CB supplier 'truck something' or 'something truck'? Squashes down and fits in the car easily.

For a big 'do' you might be able to borrow a mobile tower. Are you anywhere near Sheffield?

Roy, some of us have routinely used things we later learned weren't supposed to work, and this is another example. If I had known about radiation angles as a beginning Novice in the 50's I probably would have never expected that head high dipole to work as it did. I thought it was normal operation.

Your point made earlier seems important, from some of what we've seen written here.. Just because an antenna's main lobe is not pointed where you want your signal to go doesn't mean it won't radiate well to that location. Lots of hams know that but lots don't, and that lack of knowledge seems to adversely affect their decisions. You wonder how many new hams never even tried to get on the air because they thought they couldn't put up an antenna that would work.

Dick

If you're working HF there is little advantage in mounting the autotuner at the feedpoint. Most current HF rigs have an autotuner built inside and match the line input. Line loss is minimal unless you're using really rotten coax. Even if you are, 35 feet of it won't kill your signal.

Dick

Hello Steve,

The SWR along the feedline between antenna feedpoint and the tuner remains practically the same wherever the tuner is located. If the tuner can accommodate a 2:1 SWR at the transmitter end it will be capable of it anywhere else.

There might be a slight advantage in placing the tuner nearer the antenna because the SWR on the line length between tuner and transmitter will be small and the loss on that length will be slightly less than without a tuner in the line.

After locating the tuner in the line will probably not notice any difference at all except at, say, 21 and 29 MHz where the line loss due to high SWR is greatest.

Line loss due to SWR with a relatively short overall line length of 35 feet may be nothing to worry about anyway. That depends on how closely the antenna matches the feedline on all bands. If the line SWR is always low there's nothing to be gained by moving the tuner.

It's a good idea to consider the purpose of the tuner. It is NOT to improve line SWR. In its usual location, immediately at the transmitter output, its SOLE pupose to is ensure the transmitter load is near to 50 ohms. It can do that job best when completely independent of line impedance at the transmitter end of the line. I would prefer to leave it where it is.

I, too, had a dipole at ten feet when I first became a Novice and it "worked".
When I raised it to twenty feet it worked a lot better. I pass that experience
on to newcomers.

Steve, when you say you have a "multi-band dipole", do you mean a dipole
per band? Or do you mean a single dipole fed with coax? If the former,
an antenna tuner at the antenna won't help much. If the latter, switching
to ladder-line will cut your losses for a lot less than an auto-tuner.

The scheme described by W7EL works in a sometimes dramatic way. Many years ago, I worked as a broadcast engineer at a highpower FM broadcast station (earning school money). (This sort of job and its license, essentially, no longer exists.) The station had/has a sister station on the other side of the state. To monitor the sister station, a yagi was placed at near 400 feet (above a very high hill) connected to a receiver, a second yagi was placed at least 100 feet lower and connected to a receiver, and then a simple switching scheme was used to select the strongest signal. A pair of lights indicated which receiver was "on." When an airplane would be in the pattern (at either end) one could see the lights cycle slowly and then rapidly while the audio was perfect. To state the obvious conclusion: This scheme works best when/while the two signals have dramatically different amplitudes (or, with care, SNR). At HF, this includes spacing the antennas far apart. 73 Mac N8TT

And just as effective as readjusting a tuner.

Another way to describe Cecil's system is that it uses a "linear tuner" made of switchable transmission line elements instead of a lumped-element tuner made of adjustable inductors/capacitors. Same job, done a different way.

Joe

I have an MQ2 on the roof of my house. It doesn't work as well as a bigger aerial and is probably only marginally better than a dipole. It has disadvantages as any compact, loaded aerial does. I have had plenty of contacts with mine however including all continents on 20m, 17m and 15m.

It has a fairly narrow bandwidth but my autotuner can match the feeder OK across the bands - works best at resonance as you would expect.

If your expectation are slightly above a wire dipole you will be happy. If you expect the thing to function as well as a full sized two element you will be disappointed. The MQ2 is however a LOT smaller than a full sized two element. I also have a Force 12 C-3SS and this is more than two times bigger in length and width than the MQ2 - the Force 12 works great but I couldn't put it on top of my house!! If the MQ2 is the biggest thing you can have then it will probably be fine for you.

Oh and by the way, I worked a fellow in the states (I'm in England) who also had an MQ2 except his was only 12 feet off the ground on a temporary pole and mine at about 45 feet! So they do work.

Good luck

> When I raised it to twenty feet it worked a lot better

But if you hadn't raised it you wouldn't have known that - until you learned about radiation angles and how some theorists present their effects. Then you might well take from that learning that your Novice antenna couldn't have worked. But it did.

a
> reasonable way.

> <snip>

I have some initial reservations on using an FOM calculation to evaluate the designs. In the design of an electrically small self-resonant monopole style antenna, the performance limitations are decreasing radiation resistance, increasing Q (decreasing bandwidth) and decreasing efficiency. [Note that there are other electrically small designs that overcome these limitations but that's a different topic] From that perspective, simultaneously maximizing radiation resistance, bandwidth and efficiency is the ultimate goal in the design of an electrically small antenna. The weighted FOM comparison could result in a situation where two designs have equal FOM but remarkably different performance characteristics, when these are considered separately. Additionally, in attempting to maximize FOM, are we not ultimately trying to maximize radiation resistance, bandwidth and efficiency?

However, I think that we will ultimately discover that the FOM calculation is irrelevant because electrically small monopole style antennas, occupying the same physical volume and being self-resonant at the same frequency will essentially have the same performance characteristics and the same FOM. Any FOM differences will primarily be a function of differences in efficiency.

To satisfy the FOM proponents, lets use the following FOM calculation to evaluate the designs:

FOM = 0.4 * R + 0.4* B + 0.2 * E

where

R = 1 - [(36 - Rr)/36]

B = 1 - [(24 - BW)/24]

E = 1 - [(98.9 - Eff)/98.9]

Rr is the antenna radiation resistance.

BW is the lossless antenna bandwidth determined from the matched SWR 1/2 power points (SWR = 5.282:1). The 1/2 power matched SWR bands are determined with respect to the antenna's resonant frequency and resonant radiation resistance (ZO for the SWR calculation is equal to Rr). BW is expressed in %.

Eff is the antenna efficiency in % determined at the self-resonant frequency from the difference in Rr and total resistance.

For the purposes of this exercise, the antennas must be in a monopole configuration over an infinite ground plane. With the exception of the first base segment (bottom of feed point), no wire section can touch the ground plane. The antenna must be base fed at the closest segment to the ground plane. The antenna must be constructed with a single continuous piece of wire. The antenna wire diameter must be 0.5 mm. Radiation resistance is determined at the antenna feed point. The antenna must fit within a volume of 6 cm height and a cylindrical radius of 1.5 cm. The antenna must be self-resonant at 350 MHz. The self-resonant frequency is determined in the situation where the antenna is lossless.

Geometry and total wire length are the variables. Maximize FOM at 350 MHz.

Just a quick note to say a big thanks to all who replied to my post.
It's funny that someone mentioned the possibility of my mate having
his preamp in. He's got a ft-920 and claimed there was no indication
on the display that it was on. I need to get him to double-check it
though since I have my doubts.

Once again thanks to all, I appreciate the confirmation.

Dear Steve,

Use ladder line or twin, windowed line from the atu/autotuner to the feedpoint. This will dramatically reduce losses at the high SWRs likely if you are tuning a single dipole for all bands. The length of the ladder is not highly critical but some lengths are better than others. Have a look at W4RNLs web pages, particularly 'Antennas from the Ground Up' chapters 5 and 6. He gives impedances at the end of twin lines of various lengths for at least two different length dipoles.

You will need a balun, between the atu and the ladder, or if you decide to float the auto atu and put the balun before it (this is what I use with my SGC 230) you must also choke the control and power lines to the atu to avoid RF in the shack and a radiating feeder.

The scheme I think you are proposing has all the advantages of a remote ATU and the convenience of coax feed into the shack. Before I got my SGC I use a balanced ATU in the shack and fed the antenna with 450 ohm twin to good effect. I'm probably more fussy about losses than you need to be as my licence limits me to 10 W (no typo that is ten). Getting twin feeder into the shack is more difficult than coax to say the least. Twin line, especially 600 ohm ladder has very much less loss at high SWR than any coax, even LDF4/50. The twin line will be operating at high SWR on some bands but your coax will be operating at 1:1 on all bands.

vy 73 and good DX

Thanks to E.H. Armstrong. An underappreciated fact is the constant amplitude characteristic of FM. A receiver well into limiting tends to have a constant demodulated output regardless of r-f amplitude variations. Microwave repeaters are feasible for analog signals because baseband levels don`t change. You can watch limiter currents flail around while a demodulated tone appears glued in place. Your VHF ham repeater also has this advantage. Don`t expect this from AM.

Best regards, Richard Harrison, KB5WZI

If I string up a dipole fed by ladder line, and support the center of the dipole on top of 2 metal masts, will the ladder line be affected if it's taped to the metal mast? If so, what kind of angle away from the mast should I have the ladder line and which direction should it go in relation to the wire? I plan on having the dipole as an inverted V.

Yes it will be affected by taping the ladder line to the metal mast. Good rule of thumb is keep it about 6" away from the mast.

Nope, only been "reading the mail" on 40M. As a receive antenna, it seems pretty good, noise-wise. Have to find a spot some evening and call "CQ" to try that band out. The 20M, 17M, and 15M are my favorite bands, however.

A vertical is really a good choice for this situation. I'm running a
R-7 (Cushcraft) on the garage for 5 years now and worked 250 DXCC
countries with 100 watts. Be aware however that you will have to stand
in line in pile-up. But that's not important if you're not interested
in DXing...

yes.

you can take one wire and bend it, or connect together several straight
wires.

a Figure Of Merit (FOM) is nothing more than a formula that combines 2 or more characteristics of an antenna in some fashion to let you compare different designs to each other by looking at a single number. The things being compared are often in different units, like ohms and hz or unitless % efficiency or db's of gain/loss. the formula provides various weights to each characteristic and usually compares them to some maximum or desired target value. There is no set way to assign the weights and target values, those are up to the designer and depend on what the objectives of the comparison are.

contest scoring is a typical example of a FOM use in ham radio. in most contests there are several targets, the total number of contacts, the number of countries worked, and the number of zones worked are typical measures of how well an operator does. Those various measures are combined with a formula that assigns points to different contacts depending on distance, then multiplied by the total number of countries and zones worked. The resulting score is a FOM that can be used to rank the participants.

You must also note that there must be constraints on unmeasured characteristics for comparisons of FOM's to be valid. In the contest score case the number of transmitters, power, number of operators, and location are typically constrained so that only stations in similar locations with similar equipment are compared to each other. In the antenna case you must constrain things like height above ground, size, type of material, and frequency in order to be able to compare a FOM based on measurable characteristics like impedance, efficiency, and bandwidth.

It stands for Figure Of Merit. In comparing different antennas, Chip N1IR, prefers to calculate a single number, derived from certain antenna properties, that provides an indication of how well the antenna performs. I would prefer to simply compare the antenna performance characteristics directly.

The performance characteristics that I would like to compare are the antenna's radiation resistance, 1/2 power SWR bandwidth (a direct indication of 2/Q), and the antenna efficiency. Agreeing to provide an FOM calculation for Chip to use, I defined the FOM as follows:

FOM = 0.4 * R + 0.4* B + 0.2 * E

where

R = 1 - [(36 - Rr)/36]

B = 1 - [(24 - BW)/24]

E = 1 - [(98.9 - Eff)/98.9]

Rr is the antenna radiation resistance, BW is the lossless 1/2 power SWR bandwidth and Eff is the antenna efficiency. The calculation of R, B and E are based on comparing the performance of the electrically small monopole to that of a full size, approx. 1/4 wave monopole, self-resonant at the same frequency as the electrically small monopole. The full size monopole has a radiation resistance of approx. 36 ohms, a 1/2 power BW of approx 24%, and efficiency of approx. 98.9%. I weighted the radiation resistance and bandwidth more so than efficiency because they are would less likely to approach those of the full size monopole.

If the small antenna has performance characteristics matching those of the full size monopole (it won't because of its small height), the FOM would equal 1. Performance degradation from the full size monopole will decrease the FOM.

MFJ sells a 33' mast that Collapses to 3.8 ft., weighs 3.3 lbs. Just pull
out each section and twist to lock.
Bottom section is 1 3/4 inch diameter.
See the details at URL:
http://www.mfjenterprises.com/products.php?prodid=MFJ-1910
World Radio sells a carbon fiber version, but they are on back order.
You can home brew your own with aluminum, plastic pipe or bamboo.
Tent poles often interlock for a potential idea.
You might also try a surplus camera tripod for the "base support" or some
rope lines and tent stakes.
Have fun, but be safe!

"Figure Of Merit".

It's a formula into which you plug all of the significant numbers about something's characteristics, and come out with a simple, single number which represents "How good is it, really?". The person or group who selects the formula, gets to decide how the various inputs are weighted.

You then plug in the characteristics of all of the candidates (sample antennas, or whatever), and whichever one has the highest FOM "wins".

In an honest evaluation/contest, it's not fair to pick the FOM formula _after_ the various candidates have been submitted for judging, because it's usually quite easy to skew the FOM formula to favor a given candidate (in fact, doing so is just another sort of optimization problem).

Rather, you should pick the FOM formula [1] in advance, and [2] with a clear understanding and agreement as to exactly what the weighting and comparison rules are. It helps reduce arguments, too, if you can [3] get everybody to agree that the weighting rules actually correspond to a fair, 'good' solution of the problem being solved... this helps reduce the risk that someone will claim, after the fact, that the rules were subtly slanted in favor of a given candidate or design approach.

In the case of an antenna competition such as this, I'd imagine that the FOM will have terms which will favor physical smallness, high radiative efficiency, convenient feedpoint impedance, and [perhaps] something to either favor, or discourage certain types of directional gain. Weight, volume, and internal complexity (e.g. number of antenna segments) would likely not be considered as terribly significant.

Vulnerability to feedline radiation (i.e. imbalance) might also be worth factoring in, especially given all the controversy about E/H antennas and whether it's the antenna, or its coax which is actually radiating.

[snip]

Let's all be perfectly clear and understand what is going to happen here.

Chip is *NOT* going to use the FOM [Figure Of Merit, a.k.a. Objective Function] himself. Rather a mathematical optimization computer routine which Chip has either purchased or downloaded as share/freeware will use the FOM as the target objective function for optimization.

Chip did not develop the mathematical optimization techniques or routines that he uses. That is not his contribution to this field. Rather these general purpose computer implemented mathematical optimization routines have been developed over many years by various rearchers and developers who participate in the very active science of mathematical optimization, and by those in the mathematical optimization business who develop the computer programs for various and general applications.

[Chip has said that he uses a Genetic Algorithm [GA] optimizer. You can get one of these for yourself. For instance - cfr the WWW site at: http://www-fp.mcs.anl.gov/otc/Guide/OptWeb/ which is a great site outlining most of the known modern methods of mathematical optimization including GA techniques. It also gives the locations from which to acquire either commercial or free/shareware mathematical optimization programs for your own use.]

Mathematical optimization routines must always be "customized" to the desired application by supplying two customization routines to the generic optimizer.

1) An FOM routine:

One has to write and supply a computer routine to the optimizer which incorporates the designer's desired FOM. Chip will provide the agreed upon FOM to the GA as a subroutine and let the mathematical optimization run until it finds an optimum [i.e. a minimum or maximum] of the FOM.

2) A pattern search routine:

During the running of the optimizer the mathematical optimization routines need to be supplied with a computer routine to set forth a "search strategy"

for exploring the space of the design parameters. i.e. after evaluating the FOM [objective function] for a given design in a set of iterations the mathematical optimization program needs a way to arrive at the next iteration in the design space to get the next design for which it needs to evaluate the objective function for comparison to the previous FOM evaluations. This is called the "pattern of searching". In Chip's case the "search routine" supplies a set of fractal iterations of the antenna in question. And so... his GA application will search over many iterations of his chosen fractal until it finds a minimum or maximum value of the FOM among the string of FOM's that it has found.

Note that there is no guarantee that the minimum or maximum of the FOM found by the search is a "global optimum" in fact it will usually be only a "local optimum".

But that's neither here nor there...

And so... again Chip will not use the FOM... rather his store bought or freeware optimizer will use the FOM.

Let the games begin...

Best,

It's 3 diploes tuned for 40-20-15-10 meters, with a common feedpoint, and I want to use it for other bands as well, so I assumed I would need a fairly wide range tuner, and that the optimum location would be at the feed point.

The tuner I had in mind is the LDG RT-11 which is coax in and out.

Ladder line is not feasible due to wire routing & other constraints...

Thanks

These statements are not correct. The engine does not work as you describe.

We do not use a conventional genetic algorithm. That would be far, far too slow, and also impossible to use for complex structures, as the genome would be astronomically large.

What we have is not shareware, nor purchased; it is proprietary.

The FOM has to be coded; normally this is an easy task.

How the engine works is not important; what is key is its ability to identify something 'better' than what's out there. It is basically a black box for this exercise. It is the I/O that's of interest.

You may wish to use shareware to run your own exercise, although I suspect that it will be 3 orders of magnitude slower, and possibly more.

Kindly let Steve concentrate on the issue at hand. I believe we will all benefit from the process.

Regards,

NC

4563. Mobile Antennas

Newsgroup: rec.radio.amateur.antenna

Over the summer, I hurt my arm and was unable to do much antenna building. I would like to
invite your attention to the Carolina Cyclone brand of screwdriver antennas! There are many
very nice offerings out there, of course, but how would you like to have that quality and save money
at the same time? My Carolina Cyclones are fully warranted and will be repaired or replaced if you
experience a problem (very rare). I take my time, each antenna is hand assembled by me, and I test each one prior to shipping to make certain it is performing up to "snuff"--an old Southern expression. So before you spend $400 for a screwdriver-type antenna, please visit www.qsl.net/k4kwh . I would love to build a high performance HF mobile antenna for YOU!

Steve,

Well, I usually can't guess the no spam so here goes. You can mount the tuner lower on the mast and it should work out ok. Another alternative is to use open wire line between the tuner (if it can handle it) and the antenna. In fact, running the open wire line into the shack has advantages too but probably wouldn't be practical in your installation.

73s,

Evan

Source record: 135214

Interesting. One night, all the way to daybreak, (long, long ago) I had
a first class library at hand. I took on the task of reading all of
Armstrong's papers. My major conclusion was, and still is, that, as is
the case with many of the inventors I have helped, he did not really
know what FM was. He could describe terminal characteristics, but not
the whys. It took Rice's little, obscure paper to make it all so clear
that one now can not at all understand the difficulty. None of this is
to denigrate the unfortunate Armstrong. Many important contributions
have been made by those who felt the answer. Even C. Shannon, another
Michigan boy who made good, once arrived at an important and correct
conclusion by a logically flawed process. He felt the answer.
When one can keep the CNR (carrier to noise ratio) at least
moderately high, FM is still hard to beat. Antennas help that endeavor.
It is late. 73 Mac N8TT

TJS <theshearers@worldnet.att.net>
shared these priceless pearls of wisdom:

->What you need to use is a 26" long whip in a magmount on the 4 foot
->square roof of a car.

Uh, no, 25", or don't you understand about the 5% foreshortening effect of any reasonable wire size?

This is a quater wave antenna and will have the
->best reception pattern (to the horizon and to the sky, and will also
->allow transmit with a decent match (SWR).

Uh, no. The radio switches to the com band (122.5) to transmit when listening on the nav band, and a small diameter wire whip will have a moderately poor (3:1 or 4:1) at this frequency. You ever done this sort of stuff before?

FRACTAL ANTENNA SYSTEMS
300 Commercial St, Suite 27
Malden, MA 02148
Phone:
PI:
Topic#: (617) 381-9595
Dr. Robert Hohlfeld
NAVY 01-110 Awarded: 16NOV01
Title: Non-Intrusive, Window Mounted, Conformal Antennas
Abstract: We propose to undertake a design study on conformal antennas for
USMC Radio Battalions. The Phase I study will identify and optimize wideband
fractal element antennas (FEA) for this application through computer (NEC and
FEM-based) modeling, guided by our firm's genetic optimization using
efficient and proprietary hardware and software. The resultant optimized
fractal elements fall within the firm's existing patents and pending patents,
thus combining a successful design solution with the rights to
implementation. Both the approach and technology access are unique to our
firm in this task. In addition to providing a design solution, the firm will
also undertake proof of concept fabrication of wideband fractal element
candidates on transparent substrates in preparation for Phase II prototype
fabrication and testing. Wideband conformal antennas from fractal designs
provide unique opportunities for application in vehicular, aviation, amateur
radio, consumer electronic markets. Convergence towards multiple frequency
use in wireless and telecom also requires a 'one size fits all' antenna
approach easily met by the technology.

I have mine at 115 feet. I'm just using LMR 400 which is slightly better
than 9913.
I would prefer LMR 600, but the 400 works fine.
6 meters is not subject to nearly as much loss as 144 and 440.

I use a Diamond DPGH62 at about 35' to the feed point, and the antenna itself is 21'. So the total length to the tip is about 56'. Anyway it performs great for local, better than most in my area from what others tell me! When the band opens,,,,,,,,,well look out!

Your mate is correct. The FT920 has an indicator at bottom left of display that says 'IPO' = "input pre-amp off"? when the pre-amp is switched off. The FT920 is pretty deaf without one of the pre-amps on, so he may never have operated it without. Compare the rigs on the same antenna before drawing any conclusions.

Hi all,

Please help. I have a transmitter and receiver working in low frequency through a set of coil. I have decided to keep the trnsmitting coil and change the receiving coil in dimension wise. Let's say if the receiving coil is about 20 mH and one inch long and wanted to change to 1/2 inch long with the same inductance, would it work for the same distance that originally was working?

Thanks in advance,
John.

norton may catch it, but it hardly qualifies as a virus as it has no way to replicate itself or spread to other machines. it is simply an annoying hoax that someone sends to various newsgroups. the only thing it is good for is pointing out to newbies why they should disable scripts on news readers.

"125 ohm // 125 ohm = 62.5 Ohm in europe. Must be some different kind of parallel?"

Andy is correct. The coax center conductors are NOT paralleled. Coax shields, both cables at both ends, are joined. The center conductors (centre conductors in Europe) become the feeders. As each has 125 ohms Zo between center and common connection, their total is 250 ohms.

Best regards, Richard Harrison, KB5WZI

Not electrically parallel, Andy, physically parallel in series.
A side-by-side series run of coax doubles the characteristic impedance.

Your experience with [your] GA algorithms being *slow* for such simple
problems is due to your of use of C++.

Hopelessly slow!

I believe that you will find that Fortran [90/95] GA implementations are
much faster... sometimes by an order of
magnitude or more, and so will not require an expensive "cluster" [a.k.a.
black box] of computers to speed things up.
Since you are using a GA implementation coded with C++ that is the reason
you have to go to expensive clusters.
You really should investigate fast Fortran implementations instead.

Heh, heh... It's always the same... Scientists and computers... Why try to
open a walnut with a sledgehammer,
when a nut cracker will do?

Has anyone else noticed that since the inception of the High Frequency Active Auroral Research Program (HAARP) that HF propagation has been really wierd? Especially during summer months.

I don't remember propagation being so bad, during daylight in particular, as it has been since 98 when HAARP fired up.

Even in this peak sunspot cycle (a two peaker yet) it has been rough as hotel. I realize summertime obsortion is a major factor. Perhaps we could blame it on the ozone layer.

Any comments?

4599. Skin effect experiment with disk on antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2002-09-06 19:43:15 UTC
From: rsparks <rsparks@elltel.net>
Message-ID: <3d790193_2@corp.newsgroups.com>
Source record: 135141

Hi all,

Many amateurs believe that skin effect on the shield of a coaxial cable effectively separates the two sides of the shield into inside and outside circuits. This is expanded to reason that current flowing on the outside of a coaxial cable can not influence currents on the inside (central) conductor.

If this complete separation were to occur, substantial voltages would have to exist between the two sides of the metal shield. The question then becomes "Can metals support voltage differences and can a test be conducted to demonstrate that a voltage difference must exist across the metal?"

I reasoned that a solid metal disk placed near the feed point of dipole antenna would demonstrate skin effect. The solid metal disk should not conduct current through the disk, but should force the current to flow around the edge of the disk. The path around the edge of the disk is longer by twice the radius of the disk so the length of the antenna should be substantially increased. This would result in a lowered resonant frequency for the dipole containing the disk.

The experiment and results are described in a web page found at

http://www.televar.com/~rsparks/public_html/Disk_Experiment.htm

If you don't have time or the ability to look at the web page, I can tell you that the metal disk did not lower the resonant frequency of the antenna.

Richard, is this going to be a receiving antenna? If so then
there are gobs of URLs to visit.

I use a simular tuning diode system to this one
http://www.carcanada.net/dx/RTL.html
on an 80 meter indoors receiving loop.

Try going to google.com, type in: antenna,diode tuned.

I knew a guy who, about an hour before a DX station was to show up,
would go off frequency and shout "ola" for an hour and claimed that he
"ionized the path" for better propogation. Maybe it did work negatively
because we always whipped him in the pileups.

Hi Roger,

rsparks wrote:
[stuff deleted for brevity]

> If this complete separation were to occur, substantial voltages would have
> to exist between the two sides of the metal shield.

Why? According to Ohm's law, the voltage difference between the two surfaces is equal to the conduction current density perpendicular to the surface, times the thickness of the plate, times the material resistivity. The cross sectional area is very large and the resistivity of copper is nearly as low as it gets at normal ambient temperatures. Substantial voltage drop would require enormous currents and correspondingly large losses.

> The question then
> becomes "Can metals support voltage differences and can a test be conducted
> to demonstrate that a voltage difference must exist across the metal?"

Ohm's law relates the voltage drop to the conduction current density and material characteristics. What is it about the skin effect explanation that suggests to you that a substantial voltage must be present between the two surfaces of the disk?

> I reasoned that a solid metal disk placed near the feed point of dipole
> antenna would demonstrate skin effect. The solid metal disk should not
> conduct current through the disk, but should force the current to flow
> around the edge of the disk.

> The path around the edge of the disk is
> longer by twice the radius of the disk so the length of the antenna should
> be substantially increased.

Why? Is there any more energy stored in the magnetic field when the disk is inserted? How about the electric field?

I think a better demonstration that the current travels on the surface is performed by altering the electrical properties of the surface and observing a change in the feedpoint resistance. For example, coat the outside region of the disk with a material having a high magnetic permeability and resistivity. This will increase the losses for current flowing along the surface, but have no effect for current traveling beneath the surface. The feedpoint resistance (and bandwidth) will be higher for the coated case than the uncoated one.

We are experiencing weird sunspot cycle (I predicted that and was laughed at)
that would affect about 95% of propagation (and climate changes) rest would be
our insignificant "efforts" at poisoning and globally warming the Earth.
If anything I would expect HAARP effects be localized around KL7 and W6, rather
than affecting whole world propagation.

It takes more than a ionized path to win a contest...hi.

Seriously tho....have you noticed that when a major DX contest has marginal over the pole propagation that on the second day it is usually much better??? Not counting a solar burp that is.

I say the fact that you got bunches of KWs going off at the same time it may indeed help 'grease the skids' so to speak.

Isnt' that some of what HAARP is supposed to do?

God Bless University of Waterloo.

Lotta water under the bridge with Fortran since WATFIV... Fortran 90/95 has all of the best of FORTRAN without the bad parts. And it's simple, fast, and easy to learn.

Make your coders use Fortran 95!

But ya gotta *make* em do it, cuz they won't do it of their own accord... heh, heh

The mis-direction new graduates get from the army of young academic faculty who have never done *real* stuff is unfortunate and has ruined a whole generation of coders.

Hey didn't you know that the ++ in C++ *really* means that it generates lots more kLOCs. Get rid of the "objects" and the code size and execution speed goes way down. Use Fortran 90/95 and you can actually read the code yourself and see all of the *horrible* mistakes those young coders are making.

As with any job done by others... remember when overseeing programmers/coders the rule is -- "Inspect" don't "Expect!"

"Computer Science is no more about computers than Astronomy is about Telescopes." -- Edgar Dijkstra

Now... about that antenna optimization contest, Steve gave y'all the objective function, now...

Get to it!

Hi Dan,

Perhaps, but it was designed to punch a hole in the atmosphere to
allow massive radiation to stream in and upset the natural, global
exposure distribution. The purpose of this was to then compare
"before" and "after" shots of the world's response and then draw out
structural anomalies in the world's structure. During the rein of
George the first, it was proposed that it could "X-ray" Baghdad to
find underground bunkers in a sort of HF Tomography.

Metals cannot behave differently from any other materials from which our Universe is composed. The Laws of Science, the Laws of Nature, the Laws of God, or whatever other description is chosen is chosen to name them, are invariable.

The propagation of electromagetic fields in, through and on the surface of any material are governed by two constants associated with that material. These are Permeabilty and Permittivity.

These two values, with Frequency, fix the propagation velocity through and the impedance of any material. For example, in a vaccuum the propagation velocity is 300 metres per microsecond and the impedance is 377 + j0 ohms.

Any predictions which ignore the two fundamental electrical properties of Permeability and Permittivity are doomed to failure.

But no doubt there will be nit-pickers including a few EH and other sorts of wierd antenna inventors/fanatics.

I don't worry about it... I just let NAV 2002 earn it's keep and I've never
had a problem.

4616. 40 m dipole near Beam Mast? A Problem??

Newsgroup: rec.radio.amateur.antenna
Date: 2002-09-07 00:01:49 UTC
From: StarGazer <pti@capnet.com>
Message-ID: <3D7941ED.2AE33B5E@capnet.com>
Source record: 135162

My 40 m dipole will run about 3 feet away from my beam
mast. And about 3 feet below a 2 element beam.

This shouldn't be a problem for either antenna should it?

Since there shouldn't be hardly any mutual conductance since
they are perdicular to each other.

>and easy to learn.

Bah. *Real* programmers write in FORTRAN IV, and mix their COMMON,
EQUIVALENCE, and DATA statements with panache!

They then run, very quickly, so they're out of blast range when these
three elements finish reacting. I can only think of one more
dangerous construct... the ALTER verb. [Oldtimers will understand the
shameful thing I'm admitting to, with this last sentence... youngsters
won't, but trust me, you're better off that way.]

>Hey didn't you know that the ++ in C++ *really* means that it generates lots

>making.

Been there, done that, during a four-year stint in college... worked
as a batch-job submission/processing and user-assistance guy in the
student computer center.

If I never again see so large a quantity of code, written without any
clear understanding of the problem that the coder was trying to solve,
I'll be greatly relieved. Brrr... the horror, the horror...

However, I did develop the ability to hear the plaintive "I've been
working on this for a week, it does XXX, I've tried everything to
figure out why it does that, I can't find it, and it's due tomorrow",
glance at the printout for about ten seconds, circle three lines of
code and say "Here it is, here's why it's wrong, and here's roughly
what you need to do to correct it." About 90% of the time I'd be asked
"How did you possibly see that so quickly??", and I could always
truthfully answer "Well, I've made the same mistake myself a couple of
times :-("

As in most things, experience (sometimes painful) was the best teacher.

Source record: 135156

hello

I just purchased and ICOM 706MKIIG and I am getting lots of help. I wanted to ask you because of your antenna expertise, about running the ladder line. The ladder line is ~33 ft but the wire is only 23 feet off the ground. Short trees. I am bringing the line off the wire at right angles and down to the ground. My plan is to double it back on itself and then the coax into the attic vent and then route the cable through the attic and over to the Shack room. This results in the ladder "lapping" itself. Since the ladder line is part of the transmitter element, will this cause problems? I am using a MFJ Versa Tuner II for the antenna matcher.

My other alternative is to run the ladder line down and then over the ground to the Shack window and into the Shack window.

N1GLC says his G5RV is also 20 feet off the ground and he gets Tokyo.

> with a one ohm feedpoint resistance, the 50 ohm SWR will be 50:1 at
> resonance.

Indeed, and the point of lowest SWR might well not be the point of
resonance either. I.e SWR is one at 50 ohms impedance, reactive or not.
SWR is a _very_ bad measure of resonance.

Two little known facts about the G5RV

1. It won't work on all bands without an ATU (a real one, not the built in
sort).
To quote G5RV himself:
"the use of a suitable antenna tuner is necessary on all the other hf
bands
because, on those bands, the antenna plus the matching-section will
present
a reactive load to the feeder"
see http://www.qsl.net/aa3px/g5rv.htm

Here are some impedances at the end of the G5RV twin line

MHz Twinlead/Coax Junction Impedance 50 ohm Coax SWR
3.8 14.6 + j2.9 3.44
7.2 27.9 - j54.8 4.3
10.125 31.6 + j274 50
14.2 103 - j49 2.6
18.14 44.3 - j290 40
21.3 24.2 + j80.7 7.8
24.95 79.3 + j41.5 2.2
28.4 3049 + j655 64

see http://www.qsl.net/k2hq/g5rv.htm for more detail

As you can see, the antenna is not resonant on any band. No
figures given for topband although most ATUs will tune it up
without strapping the feed together. Varney chose a good length
for the feedline which got reasonably low reactances on all the
non-WARC bands, but the ATU should be at the junction of the ladder
line and the coax. SGC make just the thing....

For more impedance figures for the 'raw' antenna - 102' dipole see

http://www.cebik.com/gup/gup6.html

2. It is _much_ better if you throw away the coax. It is also then not a
G5RV.

Operating coax at SWRs like those shown is a sure way to
dissipate power without radiating it.

In fact, here's the code that the message contained. If you know
HTML/Javascript, you can see that it's clearly not a virus, just a message
box that pops up in a loop. Ignore the //# at the beginning of each line.
I put that in to make sure no tools actually ran the script...

//#

//#

If NAV lists it as a virus, then that's good enough for me. It's a VIRUS!

4622. G5RV ladder line

Newsgroup: rec.radio.amateur.antenna
Date: 2002-09-07 00:49:07 UTC
From: Wayne Sellin <sellinwg@starpower.net>
Message-ID: <albhto$f7h$1@bob.news.rcn.net>
Source record: 135163

From what I have been reading please help with the following.
I understand that the ladder line is part of the transmission line and the transmission line is not part of radiating antenna. Therefore I should be able to bring it down and into the attic vent, across the attic and down into my shack.. Please see my original message and question below.
This is also saying the there is no special length to the ladder line?

news:albg4dafs1@bob.news.rcn.net...
hello

I just purchased and ICOM 706MKIIG and I am getting lots of help. I wanted to ask you because of your antenna expertise, about running the ladder line. The ladder line is ~33 ft but the wire is only 23 feet off the ground. Short trees. I am bringing the line off the wire at right angles and down to the ground. My plan is to double it back on itself and then the coax into the attic vent and then route the cable through the attic and over to the Shack room. This results in the ladder "lapping" itself. Since the ladder line is part of the transmitter element, will this cause problems? I am using a MFJ Versa Tuner II for the antenna matcher.

My other alternative is to run the ladder line down and then over the ground to the Shack window and into the Shack window.

N1GLC says his G5RV is also 20 feet off the ground and he gets Tokyo.

> resonance.

Indeed, and the point of lowest SWR might well not be the point of
resonance either. I.e SWR is one at 50 ohms impedance, reactive or not.
SWR is a _very_ bad measure of resonance.

Two little known facts about the G5RV

1. It won't work on all bands without an ATU (a real one, not the built in
sort).
To quote G5RV himself:
"the use of a suitable antenna tuner is necessary on all the other hf
bands
because, on those bands, the antenna plus the matching-section will
present
a reactive load to the feeder"
see http://www.qsl.net/aa3px/g5rv.htm

Here are some impedances at the end of the G5RV twin line

MHz Twinlead/Coax Junction Impedance 50 ohm Coax SWR
3.8 14.6 + j2.9 3.44
7.2 27.9 - j54.8 4.3
10.125 31.6 + j274 50
14.2 103 - j49 2.6
18.14 44.3 - j290 40
21.3 24.2 + j80.7 7.8
24.95 79.3 + j41.5 2.2
28.4 3049 + j655 64

see http://www.qsl.net/k2hq/g5rv.htm for more detail

As you can see, the antenna is not resonant on any band. No
figures given for topband although most ATUs will tune it up
without strapping the feed together. Varney chose a good length
for the feedline which got reasonably low reactances on all the

non-WARC bands, but the ATU should be at the junction of the ladder line and the coax. SGC make just the thing....

For more impedance figures for the 'raw' antenna - 102' dipole see

http://www.cebik.com/gup/gup6.html

2. It is _much_ better if you throw away the coax. It is also then not a G5RV.

Operating coax at SWRs like those shown is a sure way to dissipate power without radiating it.

Message-ID: <albm4d$95a$1@slb7.atl.mindspring.net>
Source record: 135167

At one time I had a TA-33sr Tribander up above the rotar. I hung a 3 element 40 meter beam made of wire. Supported by a radio shack mast bolted through the tower.

I was not happy with the 40 meter antenna at all. And the 20m pattern of the tribander didn't act right afterwards. I took the mess down,

I may have had something screwed up somewhere, but I think it did effect each other.

Source record: 135069

I just got a Create Log Periodic. I got the smaller one which is for 100-1300 MHz. I puzzled by one thing, there is no balum or transformer. Most scanner beams I have bought usually include a 300-75 ohm TV type transformer to match the 300 ohm beam to the 75 (really 50 ohm) scanner input.

Am I missing something or does a Log Periodic have a 50 ohm feedpoint?

I think I may have a couple of minor points for Steve for off-line, but I see no reason why a mid/late Oct time scale isn't do-able.(as I mentioned earlier). Should be fun and everyone will learn something.

In the meantime, I appreciate the obvious drop off of un-related comments and hope we can all maintain a cordial 'even strain' as they say.

You can imagine why I must hide my identity.
First the real meaning of H.A.A.R.P is Hey Amateurs Are Really Pissed. is classified secret.

The purpose of this nefarious project is to cut the balance of payments with Japan. It was found that the number of hams decreased dramatically as propagation disappeared.

It was found that with the use of a greatly amplified Raser (see note 1), holes could be burned into the atmosphere of sufficient size to allow 92% of the radio waves to escape reflection. Actually the most horrible secret is... Wait there is someone knocking on the door, be back in a secon

4632. Cushcraft R8 Bandwidths

Newsgroup: rec.radio.amateur.antenna
Date: 2002-09-07 03:10:26 UTC
From: John Shepherd <john@eternalchaos.com>
Message-ID: <q7ee9.9698$zv.1731550@news20.bellglobal.com>
Source record: 135075

Has anyone measured actual VSWR 2:1 bandwidths on the Cushcraft R8 using an MFJ antenna analyzer?
I have just installed an R8 and find that many of the bandwidths are less than advertised.
On 40m, I measure a BW of 107 KHz. at the transmitter end of 62 ft. of RG-213, and calculate a BW at the antenna of only about 83 KHz. The spec is 150 KHz.
On 20m, I measure 270 KHz. at the transmitter and calculate about 223 KHz. at the antenna. The spec is >350 KHz.
The antenna is mounted on a flat roof with the radials 9 feet above the roof. There are, hovever, metal roof flashings about 13 feet away.
Has anyone taken comparable measurements on an R8?
John Shepherd

Message-ID: <9arinukq956cheu7n4g5u6jbusrhp9hrqj@4ax.com>
Source record: 135073

Might work on some bands, but obviously not the best answer.
I have a G5RV at 14' and the ladder line was run down the fireplace
and back up to the roof to enter the attic. Worked O.K. on many
bands, but could not tune the MARS bands outside 80 Meters. The
antenna is now in the same place, but the ladder line is across the
roof at a right angle to the dipole section. Seems to work better, but
I still cannot tune 40 Meters with the internal tuner and have some RF
splashing in the shack on 40,80 Meters. Works ok up through 20,
though, and it is useable on 80 and on 40 with an external tuner.

Keep all ladder-line at least 4+ inches away from other
sections of ladder-line. Do not roll it up like coax.
You can hang it, accordion style, from a string or coil
it in a spiral. But do not "double it back on itself".

Take a look at my web page to see why the series section on a G5RV is
a special length. It resonates the G5RV on or near 80m, 40m, 20m, and
12m. Keep the ladder-line a few inches away from metal.

If you use ladder-line all the way to the transmitter, you will have
moved the matching function from the coax/ladder-line junction to the
transmitter. You can still have matching problems even with an antenna
tuner.

There have been cases of electrocution in this area where plumbers have removed the water meter and so broken the metallic connection. (The electrical supply distribution scheme is MEN.) I suspect that the cases of serious electrocution were probably under fault conditions, but I recall that the documentation from the supply authoritiy suggested that the 'residual' currents measured could be dangerous to people with a weak ticker. In any case, they mandate a procedure of electrically shunting the intended pipe break before opening the pipe connection.

Yes, but it`s pointless to restate the skin effect rules when all experience shows that coax bars r-f penetration of the shield. The cable TV company here delivers Channel 2 on Channel 12 without interference from broadcast signals. Broadcast stations many times bury the coax feeding their antennas without any measurable loss to the earth it`s buried in or any effect on the impedances seen at the ends of the coax.

The r-f voltage breakdown in coax is between the center conductir and shield. The r-f potential difference between inside and outside shield surfaces does not break down the inherent isolation provided by skin effect.

Log Periodics like those from KMA Antennas, and I assume the Create,
use "dual booms". This method of construction allows the booms to be
the "feed line" between the series of dipoles. The impedance of this
"feed line" is determined by choosing the boom(s) diameter and
center-to-center spacing. Thus you end up with an antenna with an
average impedance of 50 ohms.

Message-ID: <3d7a09da_2@news1.prserv.net>
Source record: 135089

Roger:

The physical construction of this particular antenna produces a 50 ohm unbalanced feedpoint. Best performance, however, is horizontally polarized, with the feedline supported close under the lower boom back to the support mast. I don't know if Create ever fixed it, but the coax to feedpoint connection tends to come loose at the center conductor. Apparently the center conductor of the coax they used back in the mid 90s when we bought a couple dozen of them didn't take solder very well. Since our applications had short feedlines, we replaced the existing coax with a UG-1034/U (non-A) BNC connector and used foam RG-224 type coax. Take a very critical look at the center conductor center solder joint, especially if the antenna is going up high enough to be difficult to get down to repair.

Vertical polarization mounting is a headache as are all LPAs. Keep the mast and feedline away from the elements. Only 2 good ways to do this, rear mounting, or side mount on a 5' mast away from vertical oriented conductors. Neither option is mechanically pleasing.

Reg, G4FGQ wrote:
"How thick does the skin have to be to achieve the insulating effect?"

Current flow in a conductor produces a magnetic field within the conductor which opposes the magnetic field moving in. Imposed and induced fields tend to cancel. Density at the surface diminishes deeper into the conductor as a result of this opposition.

Current density decreases exponentially with depth below the surface. Skin depth is defined as 1/e, or the depth where current is 36.8% of the surface current. The higher the conductivity, frequency, and magnetic permeability, the less penetration there is of a conductor.

For copper, B. Whitfield Griffith, Jr. tells us:
1 Hz, 2.60 in.
10 Hz, 0.826 in.
100 Hz, 0.260 in.
1,000 Hz, 0.0826 in.
10,000 Hz, 0.0260 in.
100,000 Hz, 0.00826 in.
1,000,000 Hz, 0.00260 Hz.

Ok guys, I guess somewhere its been asked before but I cannot find
anything on the newsgroups.

I have Nittany NEC the WIN3.1 version 1997 at Uni.

I am having trouble because some blighter has not returned the docs
on the following...

1) Just what are the damn coordinate ? I seem to be failing on the most
basic of parameters.

2) Can I use the helix parameter and connect it to a generated wire
ie does the helix have a central point ?

3) Why does the NEC WIN BASIC spreadsheet thingy not like the GH command ?

4) Has anyone got any .NEC files for HF verticals for the amateur radio
bands helically loaded ?

Any relies much appreciated via this NG or preferebly to the email
address shown along with this NG posting.

not written here, as I know I will just get more spam :-)

Lou, N4LQ wrote:
"I measure exactly 20 ma of d-c current and it stays constant."

It could come from your gas distribution company. Gas pipes are nominally insulated from earth and a potential is applied to them to avoid galvanic action which would eat away the gas pipe. A "rectifier" applies this potential between the distribution piping and a ground bed of carbon electrodes.

A gas water heater or other appliance may connect the gas and water systems in your house. If the gas company`s meter insulation is violated, the gas distribution cathodic protection current will leak through your water piping to the earth. The potental at the gas meter is only a fraction of a volt and poses no electrocution danger. An electrical fault could put a dangerous potential on your plumbing were it the only electrical earth connection. The power company here requires a ground rod in addition to the water piping for a meter ground. The power company also grounds the secondary of its distribution transformer and grounds distribution wires at nearly every pole and numerous other grounding opportunities. Chances of appearance of a dangerous potential on a "ground" wire is almost zero, but it`s always wise to assume that the conductor could be dangerous and put a short to ground on it to prevent it from becoming dangeroudly energized while you are handling the conductor.

Best regards, Richard Harrison, KB5WZI

I want to put up a antenna at least 70ft high but their are too many phone lines and power lines running through my back yard. I could put it on the roof of my house tree or next to the grage which is the only building in my back yard that has the most space away from phone or power lines. Which way would be the best to put up a 5/8 wave antenna and how would I do that.

I used to use a bow and arrow. Anyway, just using the slingshot at dusk, once to get the line over the tree, shoudn't, and I repeat, shouldn't be noticed.

I now joined a loop forum so much I can get there. But actually, in this post I was not thinking about loops, just a long wire with LC tuner, C being varicap diode. Just wondered about that kind of setup.

Move the metal disks to the ends of the antenna and it will lower the
resonant frequency.

Source record: 135105

NEC-Win Basic is just what the name implies - it is a basic program and does not contain all the NEC commands. I don't believe that Nittany any longer sells this program having replaced it with NEC-Win Plus+ which is a more advanced entry level NEC program, but it still doesn't offer the full NEC command list which is also is true of standard version of EZNEC. (Commands like GA, GC, GH, GM and others are not available.)

By the way, demo versions of both programs (EZNEC and NEC-Win Plus+) are available on the web.

If you want to use the GH card then you will need to ether build your entire NEC card deck with text editor and then run it using a generic NEC engine and then decipher the output data (bummer) or obtain a more advanced implementation of NEC such as Nitanny's NEC-Win Pro which does contain all whole NEC command set.

As an alternative, for you application, take a look at Nittany's NEC-WinSynth. This is an excellent program for creating wire structures including a helix using only the GW card. With NEC-Win Synth you can save the wire geometry in several formats including a NEC text file which can be used by NEC Win-Plus+ or EZNEC (Synth will also save the geometry in a text in a special file format which can be imported into EZNEC) and other programs which can read a NEC text file. I have found NEC-Win Synth to be an excellent program and real time saver to.

Hope this helps.

>Where I am slingshots are not supposed to be used. But....
>Any suggestions or insights or sources?

[1] Fishing rod, stout line, and a sinker of suitable weight on the end of the line. Try an overhead cast.

[2] Try making an atlatl (a.k.a. woomera or spearthrower), and use it to throw a line/sinker. [Throwing a dart with an atlatl is probably _not_ a good idea, in this context!]

With any such method, apply all of the cautions you'd use if you were using a slingshot - plan out the shot, and be very aware of where the weight would end up going if your shot/cast goes off in the wrong direction. Cast only nonmetalic lines - don't try to loft a wire directly - if you try lofting a wire and it comes down on a power line by mistake, Very Bad Things can happen.

Yes, but then it would not demonstrate that skin effect fails to separate
the disk surfaces.

Hi Richard,

You don't stand a chance for a very simple reason.

Varicaps as you call them, adjust their capacitance through varying a
bias voltage separating two charge regions (or drawing them together)
within the diode. This voltage is roughly tenths of a volt to a volt.
The voltage imparted to a tuner by a transmitter exceeds the tuning
voltage by magnitudes to render them useless for this action. This is
why the other poster, Walter, queried you if this was for reception
(where the RF levels are milli to microvolts).

The standard version of EZNEC doesn't read or use NEC format files at all. The professional versions are able to read input files in NEC format (which it then translates to its own format), but as Danny says, only a limited set of "card" types.

Well... ya got me there!

However, you should note the nature of my objection: volts. If you
are running a longwire, it is absorbing every radiation available
(insofar as it has the ability to put it to a load) which could quite
easily disturb the bias settings for any particular filter setting.

These voltages, induced from nearby transmitters (local AM station for
instance) could offer 10's to 100's of millivolts, which while a
seemingly small potential, can cascade into an enormous bias error.

This is the paradox of the stronger the signal that makes it through
the filter, the more probability that signal will disturb the filter.
As this signal is an AC voltage, it blurs the capacitance with the
diode trying to follow the dV/dT of the signal - effectively lowering
Q (negating the filter).

The answer to this as a direct application would be in buffering and
lowering the maximum level of signal that may be passed through the
filter. This may be accomplished through AGC or manual gain control
(yeah, a filter with a gain control). Research any particular device
you wish to use for your application and find its dC/dV (as derived

from the specs for capacitance range and voltage range). You should be able, at that point, to have a good guess how much impact a signal of certain size would change any setting.

Same problems of voltage levels keep PIN diodes relegated to buffered environments.

Hi
Wonder if anyone can answer a query about dipoles for me. I understand that you can use a common feed point for multiband dipoles, but wonder if you were to space 2 dipoles at right angles for the 40m band with the common feed point would this give the required 360 degree coverage. Many thanks in advance for your help.

For all practical purposes a simple single dipole element will be omni directional. The ground, surrounding buildings, wires, terrain etc all will 'screw up' the pattern.

You can indeed mount another dipole at right angles. But I see no purpose in it.

A better choice would be a antenna called a Turnstile. Usually used on V/Uhf.

4678. TXing & SWLing MW to 10m w/Attic Ant for Low Noise - HELP!

Newsgroup: rec.radio.amateur.antenna
Date: 2002-09-07 23:46:33 UTC
From: thx1138 <look@life.org>
Message-ID: <3d7a9063$0$1428$272ea4a1@news.execpc.com>
Source record: 135021

I have been reading the archives and web sites attempting to weigh the pros and cons of several attic antenna options for my location. To say the least I have been tearing my hair out trying to decide which way to go. Call it information overload. I am posting here in hopes that your comments and experiences will help me sort it all out.

Here is my dilemma: I am building a new home (wood w/vinyl siding) on a typical city lot with deed restrictions on external antennas. So, I am relegated to using an attic wire antenna for my hobby purposes. The lot has a big plus in that it is located on lands which happens to be the highest elevation within the county. A fairly big negative is that there is an electrical substation located approximately 1/2 mile away with high voltage lines passing by about a 1/3 mile away. I have radio surveyed the area in various weather conditions for any serious noise problems emanating from these potential noise producers. But surprisingly have not noticed any noise unless I stand directly under the lines. You may wonder, why not build somewhere else? Unfortunately, that is not an option for personal reasons.

My hobby: I enjoy doing it all from MW and SWLing to a very occasional ragchew on CW. I don't chase DX any longer but I won't rule it out if the opportunity presents itself. (I've worked Antarctica on 80m with a Mor-gain dipole once, what a thrill! But that is the extent of my major DX accomplishments and my antenna experiences.) In fact I have been inactive for many years but have the itch to pound the key again. But txing with a highly efficient radiator is secondary to listening to most anything from MW to SWLing everything from Intl BC to Maritime and Milcom, etc.

Most recently I have been using a simple 50' longwire hooked up to an old Icom 720a. The longwire worked reasonably well for listening but the man-made noise was a pain. And that is the crux of my dilemma, reducing noise: Improving the S/N ratio for listening on MW to 20m without adversely effecting my occasional cw foray on 80m or 60m(?)-10m (incl. warc). With so many modern electrical appliances in a typical home in an urban environment the noise can become a major problem for SWL'ers and DX'ers. My goal is to neutralize this problem the best I can without too much compromise with the antenna space limitation at my location.

Here is what I have to work with. The house is a one story ranch with a maximum linear length in the attic of 54'. The roof has a 12/6 pitch (or is it 6/12?) and the resulting height in the attic at the crown is about 6'. The shack will be in the basement with the transceiver located approximately 22' directly below the antenna's feedpoint. The feed will run through an interior studded wall, from attic to basement, avoiding any house wiring. I can also relocate the shack to one end or the other of the basement if

necessary to accommodate an end fed type antenna. For you antenna modeling types, the ground conductivity in my area (upper Mid-west) is what I would say good. Ideas are welcome!

Considering all of the above I have come up with three possible attic antenna solutions:

1) WB Folded Terminated Dipole (zig-zag?), coax fed (fair tx/rx but low s/n?, wide BW [~5MHz-30Mhz], no tuner)
2) Zig-Zag Doublet fed w/parallel feed (susceptible to noise?, need ATU, potential qrm cause, good tx/rx)
3) W9INN Dipole (zig-zag?) , coax fed (need ATU, have heard good comments, all around compromise?)

In all cases, if possible, I could form the antennas into a "Z" shape in the horizontal plain for a total length of aprox. 74'. The "Z" shape in the Doublet would actually skew the lobes on most ham bands in a direction to my favor, I think. See: http://www.cebik.com/zzdd.html

-Questions:

Would a "Z" shape effect the WBFD or W9INN dipole in a similar manner as the Doublet?
[Just for kicks, could anyone run a antenna model on a "Zig-Zaged" WBFD using my parameters?]

I have never used parallel feedline before. What is the potential in causing qrm in this Doublet installation?
Will using parallel feedline be more susceptible to man-made noise?
Which antenna tuner for the Doublet would you recommend for 100W?

Considering the very limited height (16' from surrounding ground level, 22' from the full sized 1600sq/ft basement floor) above ground of any of these antennas, would any one be a better choice over the other? Will they all be cloud warmers?

Would using a pre-amp/pre-selector such as a Vectronics AT-100 be advisable with the WBFD to possible offset its negative gain (relative to a dipole) as well as possibly reducing band noise using the pre-selector?

-Answers? :-)

I know many of you will have strong feelings for one antenna over another and that is fine. I would simply ask that you keep in mind my desire to fight off the electrical qrm that tends to permeate our urbanized ether. Yet at the same time attempt to choose/build an antenna that performs "fairly well" on both tx as well as receive. Working dx is great, but being able to actually hear them is even better. Theoretical discussion is enjoyable but practical advice from anyone who actual uses any of these antennas types is much appreciated.

Tnx,
Stan

Why not just put a loop around the eaves and paint it to match the wood work, use 300-ohm twinlead (hidden in the corner of the siding, then run to the basement? Hidden from prying eyes.

Jack,
It's very unlikely that you will find one antenna that
will cover something close to 4 Mhz without tuning. And
no, the groundplane kit does not help with that antenna.
'Doc

PS - You will hear all kinds of claims for antennas, most
you could spread on a garden with good results.

Two dipoles at 90 degrees to each other, simply connected, behave the same
as a single dipole at an in-between angle 45 degrees to both.

If the connection between them is switched then the direction rotates
through another 90 degrees.

360-degree coverage in the horizontal plane is obtained by separately
feeding the two dipoles with a phase difference of 90 degrees.

Try cutting one pair for the high end of the band and the other pair for
the low end. Not sure if it will work on 40 but it does work on 80 Meters.

Source record: 135030

Roger, W7WKB wrote:
"Yes, but then it would not demonstrate that skin effect fails to
separate disk surfaces."

Metal shields have been used to prevent radio frequency travel from one side of the metal to the other from very early times. There were tube shields, coil shields, etc. The metal chassis itself is a shield.

The 19th edition of the ARRL Antenna Book says on page 23-2:
"In good conductors the speed (of r-f wave travel) is so low that the opposing fields set up by the wave front occupy the same space as the wave itself, and thus cancel it out. This is the reason for "skin effect" in conductors at high frequencies, making metal enclosures good shields for electrical circuits working at radio frequencies."

Coax and waveguide don`t allow r-f in or out through their walls. They are inpenetrable. Disks aren`t needed anywhere to prove this. Why can`t you normally pick up cable TV signals without connections to the cable? Shielding!

Best regards, Richard Harrison, KB5WZI

4688. Water pipe ground?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-09-08 02:42:23 UTC
From: N4LQ <N4LQ@igLou.com>
Message-ID: <3d79676d$1_3@news.iglou.com>
Source record: 135074

I cut the main water pipe to install a whole house filter. The filter is plastic and came with a jumper wire to complete the electrical bypass. Since I use this pipe for my ground, I was curious if it really worked or if plastic was used to the street main. So before installing the wire, I connected an ampmeter across the filter. The meter went nuts until I put a rectifier in series with it. I measure exactly 20ma of dc current and it stays constant.
Has anyone tried this? Why is it DC current and why is it constant? Keying the rig with 1 kw input has no effect on the current. I intend to leave the meter in line for a while and see if it ever changes. Maybe a good rain will make it change?

4689. Re: Whats the best 40M mobile?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-09-08 03:19:42 UTC
From: Headhamster <headhamster@earthlink.net>
Message-ID: <ilze9.14534$6i4.1169594@newsread1.prod.itd.earthlink.net>
Source record: 135031

I ran almost exclusively 40 meter mobile from my pick up till I sold last year. I had tried a hamstick and was unimpressed. Hamsticks may allow you to "make a contact" from the mobile but they are not serious antennas if you want to hold a QSO from the mobile. I then switched to the GLA bugcatcher with the biggest available coil and a capacity hat. It was like night and day. Not only could I have a QSO, I had many stations that couldn't believe I was in a mobile. The bugcatcher wins hands down for serious HF mobile work.
